However, these cryoscopic measurements have been criticized because any autolysis occurring during the interval between removal of the tissue from the animal and the end-point of the measurement will increase the number of solute molecules present and hence yield spuriously high values for the tonicity of the tissue. That a rapid increase in depression of the freezing point of tissues will occur even at 0° C. has been demonstrated by Conway and McCormack[7], and Conway *et al.*[8], and by Brodsky *et al.*[9]. Conway and McCormack[7] found that the freezing point of guinea pig kidney and liver suspended in isotonic saline was the same as that of serum. Furthermore, by taking into account the expected rate of autolysis, they claimed that the corrected freezing-point depression of other tissues of rat and guinea pig was also the same as that of serum. Brodsky *et al.*[9] were not able to confirm these extrapolated values (although Buckley, Conway and Ryan[10], on recalculating Brodsky's results, claim that the latter agree with those of Conway and McCormack[7]). By heating tissues in water at 98° C. for 30 min. immediately upon removal to reduce autolysis, Appelboom[11] recently has reported isotonicity with extracellular fluids.

Because of the conflicting results which have been reported and because recent workers, in attempting to circumvent autolysis, have utilized complex methods which may introduce unknown variables into the measurement, the following method employing the melting point was devised. Tissues were removed from anæsthetized animals and dropped immediately into liquid nitrogen. While still at the temperature of liquid nitrogen, the tissue was pulverized by mortar and pestle and the powder suspended in liquid silicone, a biologically inert fluid. For each measurement, a portion of tissue calculated to contain a specified amount of water was used. The plastic tube containing the mixture was placed in an evacuated, silvered jar. The mixture was then stirred rapidly and thus warmed at a constant rate by a stirring device of low thermal conductivity. The increase in temperature of the suspension was measured with a thermistor and recorded by a continuously balancing electronic potentiometer.

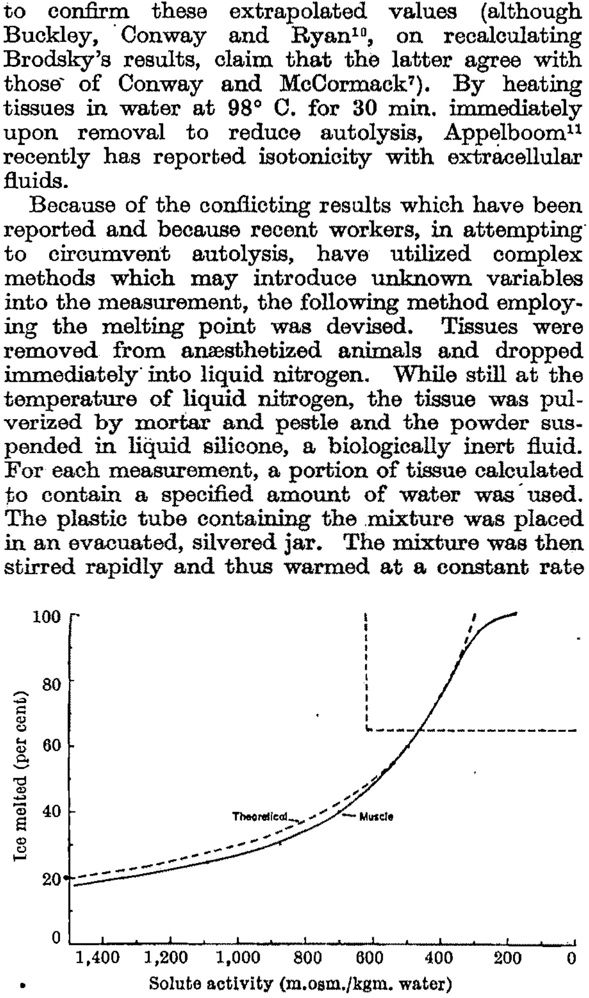

Fig. 1. Shape of the actual melting curve of rat muscle superimposed on a theoretical melting curve, a rectangular hyperbola

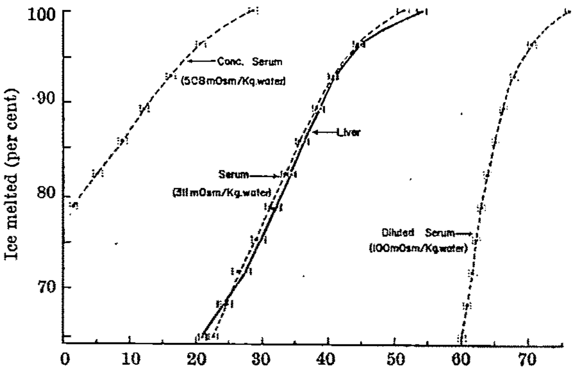

Fig. 2. Melting curves of rat liver, rat serum, concentrated rat serum and diluted rat serum

Since pure water separates as ice from a solution as it freezes, one may calculate the expected melting curve of the solution. For a given solution, when the percentage of ice melted is plotted against increasing temperature, or decreasing thermodynamic activity of solute or increasing thermodynamic activity of water, a rectangular hyperbola is obtained. Such a curve is shown as the broken line in Fig. 1. Corrections for the small changes in activity coefficients which would occur over the range of concentration shown would not appreciably alter the shape of the curve and have been neglected in the present treatment. For solutions of different activities a family of rectangular hyperbolas should result.

Fig. 1 also shows an actual melting curve of rat muscle—the solid line—superimposed on the rectangular hyperbola of the theoretical curve—the broken line. The fit is close, especially in the upper portion of the curve, and it is this portion, enclosed by the broken lines, which was used as an index of depression of melting point to avoid the uncertainty of extrapolating to the point of complete melting. Over this restricted range of concentration the effect of changes in activity coefficient will be minimized.

Fig. 2 shows the mean curve obtained from twelve separate measurements of the melting curve of rat liver and a similar number of measurements of rat serum. The ordinate represents the percentage of ice melted, and the abscissa the arbitrary potentiometer scale which is proportional to temperature or activity. The mean concentration of the rat serum was found to be 311 m.osm./kgm. water by an accurate freezing-point method. To indicate the concentration scale, the melting curves of serum concentrated by drying to 508 m.osm./kgm. water and diluted with distilled water to 100 m.osm./kgm. water have been included. The small vertical bars or rows of dots indicate the standard error of the mean for each point. It is evident that the melting curve of rat liver does not differ significantly from that of rat serum. Results with skeletal muscle, heart and brain also agreed with the value for serum. The melting curve of whole rat kidney was displaced approximately 10 per cent above that of serum, a difference attributed to the production of hypertonic urine in the medullary portion of this organ. When frozen tissue was exposed to room temperature for periods of 10 and 20 min., the subsequent measurement showed a

Part played by Deoxyribonucleic Acid in Transplantation Immunity

THE tissue incompatibility revealed by homografting is due to individual antigenic differences that cause the recipient to produce an immunity response to tissues grafted from another individual. Billingham, Brent and Medawar[1] used a transplantation immunity test in inbred strains of mice when studying the antigens responsible for the homograft reaction, and formulated the hypothesis that nuclear nucleoproteins or lipoproteins associated with them were responsible for transplantation immunity. The activity of nuclear fragments was not destroyed by the action of ribonuclease or trypsin but was destroyed by the action of deoxyribonuclease. We therefore decided to test whether tissue deoxyribonucleic acid itself acts as an antigenic stimulus in homotransplantation.

The transplantation immunity test devised by the above-mentioned authors was used, together with their method of evaluation. It is known that antigens responsible for transplantation immunity are present in different tissues of the same individual. We therefore prepared deoxyribonucleic acid from the liver, spleen and thymus of mice of the inbred strain *A* or *C*57 Black (males) using the method of Zamenhof *et al.*[2]. The harmlessness of this method of isolation was tested by demonstrating that it did not inactivate the pneumococcal transformation factor added at the beginning of the preparation[2]. It was therefore believed that this method should also preserve other biological characteristics of the deoxyribonucleic acid molecule. In addition, various procedures known to destroy transplantation antigens (tissue freezing, lyophilization, heating) were avoided. Deoxyribonucleic acid was dissolved and injected into mice of another strain (*CBA*) via the intraperitoneal route immediately following isolation, the preparation taking three days when a three-stage purification was used, and eight days with an eight-stage purification. The majority of these preparations contained traces of bound proteins (Table 1). Test transplantations of fresh donor skin were carried out on the fourth to fifth day after injection. Grafts were removed at the end of the sixth day after transplantation, prepared for histological examination and compared with negative and positive controls. Skin grafts on normal uninjected individuals served as negative controls and skin grafts on individuals previously immunized with tissue grafts from the same donor were positive controls.

The results show that deoxyribonucleic acid does not produce transplantation immunity comparable with immunity caused by a previous injection of donor tissue into individuals of the other strain. Only in a few cases was it possible to observe vacuolization of cells, pycnosis of nuclei of epithelial cells and an evident cellular host reaction (± in Table 1). In these respects the test grafts differed from the negative controls. The reaction after injection in these few cases did not seem to depend on either the dose of deoxyribonucleic acid or the quality of the preparation. Complete destruction of the test graft and especially its epithelial cells, as in the positive controls, was never observed, although the dose of deoxyribonucleic acid per mouse was comparatively large. This indicates that deoxyribonucleic acid by itself or with traces of bound proteins is insuffi-

[2] Zamenhof, St., Griboff, G., and Marullo, N., *Biochim. Biophys. Acta*, **13**, 459 (1954).

Experiments in this laboratory on the lines described above by Hašková and Hrubešová confirm their finding that preparations of deoxyribonucleic acid may provoke a feeble transplantation immunity that is detectable by homografts of skin. Splenic nuclear fragments from mice (usually of strain *A*) were washed six times in 0·15 *M* sodium chloride or in 0·15 *M* sodium chloride – 0·01 *M* sodium versenate at *p*H 7·0. Deoxyribonucleic acid was prepared from these nuclear fragments either by the sodium xylene sulphonate method (personally communicated by Dr. N. S. Simmons) or by dissolving them in 2 *M* sodium chloride, spinning at 25,000*g* for 30–60 min., and deproteinizing the supernatant by up to nine successive emulsifications with chloroform–amyl alcohol mixture[1]. The former preparation was completed by precipitation with 0·54 vol. *iso*propyl alcohol in the presence of 0·3 *M* neutral sodium acetate, and the latter by precipitation with 0·2 vol. ethyl alcohol in the presence of 0·15 *M* sodium chloride – 0·1 *M* calcium chloride[2]. In either case the fibres of deoxyribonucleate were blotted free from excess of fluid, cut up into coarse fragments under a balanced salt solution, and allowed to swell into stiff transparent jellies. In this form they were injected into recipient mice (usually of strain *CBA*), each mouse receiving about 5 mgm. deoxyribonucleic acid. The survival scores[3,4] at six days of test skin homografts transplanted three to five days after the injection ranged from 25 per cent (indicating a definite state of sensitivity) to 100 per cent (the normal or 'control' response). Great pains were taken throughout the preparations to ensure that the deoxyribonucleic acid was in an undegraded state.

Although other possibilities have been considered (including a transformation of host cells into cells with some of the antigenic properties of the donor) there is reason for believing that the feeble sensitivity provoked by these preparations was due to an antigenic impurity, probably of a polysaccharide nature. Recent evidence[5] suggests that the determinant groups of the antigens responsible for the homograft reaction (like those which are responsible for 'enhancement'[6]) may be mucoid substances: they are inactivated by exposure to low concentrations of the periodate ion and by incubation with extracts of *Trichomonas foetus* known to contain enzymes which destroy blood-group substances in man[7]. (The *Trichomonas* preparations were very kindly supplied by Dr. W. M. Watkins.) This interpretation is not inconsistent with the fact that 'transplantation' antigens are present in washed nuclear fragments[4] and follow the deoxyribonucleoprotein through at least the earlier stages of purification, for hexosamine is now known to be present as an impurity in even quite highly purified preparations of deoxyribonucleoprotein[6]. The nucleoprotein may possibly act as an adjuvant[8], if only by presenting the antigen in a physically suitable form, and the same may be true of the deoxyribonucleate when it is injected by the method described above.

Because of its relevance to a hypothesis of 'transformation', it may be added that the repeated injection into mice, from birth onwards, of high doses of undegraded homologous deoxyribonucleic acid failed in twenty-five trials to produce any sign of transplantation tolerance, that is, failed to prolong the life of skin homografts afterwards transplanted from mice of the same strain as those which provided the deoxyribonucleic acid.

Influence of a Crude Hypothalamic Extract on the Acid Phosphatase Activity of Rat Pituitaries

In rat pituitaries incubated *in vitro* with hypothalamic extracts the ascorbic acid content falls. Extracts of other parts of the brain are less successful[1]. This experiment was used to confirm *in vitro* the earlier findings in intact animals that hypothalamic extracts are able to stimulate the release of several trophic hormones from the distal lobe of the pituitary[2]. In the present study we tried to use acid phosphatase activity as an indicator.

Fresh rat pituitaries were incubated in the Krebs-Ringer-phosphate medium for one hour, adding either a suspension of temporal lobe of the brain (mean weight 104 mgm.) or of the hypothalamic region, including the median eminence of the tuber cinereum and the walls adjacent to the third ventricle (mean weight 86 mgm.). Each pituitary was exposed to the influence of 1 ml. of suspension for 60 min. The surface of the pituitary was then dried, the gland homogenized and the activity of acid phosphatase estimated by the method of King and Armstrong (K.A.).

In the pituitaries of male rats the activity after incubation in the pure medium corresponded to 2·04 ± 0·168 K.A. units/gm. The addition of temporal lobe suspension to the medium yielded values of 2·08 ± 0·097 K.A. units/gm. The mean figures, however, for incubation with hypothalamic extract were 2·79 ± 0·175 K.A. units/gm., the difference being thus highly significant ($P = 0·01$). Acid phosphatase activity of the brain tissue itself has no influence on the results, since in the temporal lobe 1·21 ± 0·05 K.A. units/gm. was found, practically the same value being present in the hypothalamic region (namely, 1·19 ± 0·099).

These preliminary results do not permit conclusions to be drawn. It remains to be seen whether the acid phosphatase activity in the pituitary, incubated *in* *vitro*, can be utilized as a new tool in the study of the influence of hypothalamic extracts.

Albinism in the Common or Hottentot Mole-Rat, *Cryptomys hottentotus* Lesson, 1826

DURING the past four years I have been compiling a preliminary list of the vertebrate fauna occurring in this National Park, situated in the Inyanga region of eastern Southern Rhodesia. During the course of these investigations it has become clear that the most common representative of the family Bathyergidae is *Cryptomys hottentotus* Lesson.

I am indebted to the assistant warden of the Park, Mr. Robert Reyers, for what would appear to be an albino specimen of this species, secured alive on April 19, 1958. This example is an adult male, with entirely white hair save in the region of the mouth and genital organs, where there is reddish discoloration from dietetic staining. The skin of the upper parts was bluish in life, and that of the under parts and feet, pink. The nails, except where suffused by blood, are white. In life the eyes were dark, with a faint suggestion of red, this latter becoming more apparent after death.

Roberts[1] lists a species *Cryptomys albus* (Roberts), the white mole-rat; and implies that he based his determinations upon three specimens, quoting (p. 398) these ". . . as the type and another specimen. There is also a buffy-yellowish specimen from Tulbagh". The distribution of this supposed species is given as "probably the Southern Cape Province only"; and attention is directed to the smaller size of the skull than in *C. hottentotus*.

The Inyanga specimen had the following measurements in life: Head and body, 125·0 mm. Tail, 12·0 mm. Hind-foot S.U., 21·0 mm.

Some skull measurements were as follows: length of skull with incisors, 37·5 mm.; zygomatic width, 24·0 mm.

The cheek teeth are simple, 4/4.

These figures come well within the range found among *C. hottentotus* secured at Inyanga, and also exceed those given by Roberts for the type of *C. albus*.

Ellerman, Morrison-Scott and Hayman[2] cite *C. albus* under the sub-heading *incertae sedis*, and Roberts mentions that Oldfield Thomas stated that the type of *C. albus* was an albino, a view shared by Ellerman, Morrison-Scott and Hayman (p. 234).

The Inyanga specimen was taken at approximately 6,000 ft. above sea-level and 32° 44′ E., 18° 17′ S.

Normal specimens of *C. hottentotus* at Inyanga are grey, darker upon the upper parts, and with a variable white head-spot which is sometimes vestigial.

Change in Mean Viability at a Multi-allelic Locus in a Population under Random Mating

A MULTIPLE allelic series at a locus can give rise to genotypes of different viabilities. Under certain conditions these genotypes can exist in equilibrium in a large random-mating population.

Owen[1] has stated necessary and sufficient conditions for such an equilibrium (when it exists) to be stable for the case of three alleles, and in attempting to generalize these conditions to the case of n alleles and to derive reasonably concise and illuminating proofs we have been led to consider the change in the mean viability of the whole population from one generation to the next. We conjecture that the mean viability increases each time the population undergoes the process of mating, but to prove this statement generally appears to be a matter of considerable mathematical difficulty. However, it is of interest to show that this is the case at least when the population is in the neighbourhood of an (existent) equilibrium, since this is sufficient for the purpose of discussing the stability of the equilibrium.

Kimura[2] and Crow and Kimura[3] state that the change in mean fitness of a population is the ratio of its additive genetic variance to the mean fitness; this is the equivalent of Fisher's[4] fundamental theorem of natural selection. However, it can be shown that their result is not applicable to the case under discussion since its derivation depends on a continuous time argument. The application of their argument to the case of discrete generations can at best be an approximation, since it is valid only for the case of infinitesimally slow selection.

Consider n alleles $A_1, A_2, \ldots A_n$ at a single locus. Let a_{ij} denote the relative viability of the genotype $A_i A_j$ $(i,j = 1, 2, \ldots n)$, and let p_i $(i = 1, 2, \ldots n)$ be the frequency of gene A_i $(i = 1, 2, \ldots n)$ in any one generation. Let V be the mean viability of the population (supposed infinite and mating at random) in this generation, so that:

$$V = \sum_{i=1}^{n} \sum_{j=1}^{n} a_{ij}\, p_i p_j \qquad (1)$$

Under random mating the frequencies p_i' of the alleles A_i in the next generation are given by the relations:

$$V p_i' = p_i \sum_{j=1}^{n} a_{ij} p_j \qquad (2)$$

The mean viability V' of the population in this next generation is:

$$V' = \sum_{i=1}^{n} \sum_{j=1}^{n} a_{ij} p_i' p_j' \qquad (3)$$

What is required is a comparison of the values of V' and V, or, more precisely, to show that $V' - V > 0$.

Suppose now that a polymorphic equilibrium exists, and consider the population when it is in the neighbourhood of this equilibrium. Let P_i $(i = 1, 2, \ldots n)$ be the equilibrium frequencies and V_e the mean viability of the population at equilibrium. Then it can be shown that:

$$V_e = \sum_{j=1}^{n} a_{ij} P_j \quad (\text{all } i = 1, 2, \ldots, n) \qquad (4)$$

Let p_i be the gene frequencies in the neighbouring state and write:

$$p_i = P_i + x_i \quad (i = 1, 2, \ldots, n) \tag{5}$$

where the x_i are small and

$$\sum_{i=1}^{n} x_i = 0 \tag{6}$$

We also write

$$X_i = \sum_{j=1}^{n} a_{ij} x_j \quad (i = 1, 2, \ldots, n) \tag{7}$$

and

$$\delta = \sum_{i=1}^{n} x_i X_i \tag{8}$$

Then a short calculation (using (4), (5) and (6)) reveals that:

$$V = V_e + \delta \tag{9}$$

In the next generation the gene frequencies p_i' are determined according to equations (2) and, after some algebra, we obtain the following expression for V':

$$V' = V + \frac{2\delta^3 - 3\delta^2 V}{V^2} + \frac{2\,V_e}{V^2} \sum_{i=1}^{n} p_i X_i^2 + \frac{1}{V^2} \sum_{i,j=1}^{n} a_{ij} p_i p_j X_i X_j \tag{10}$$

Equations (4) and (5) are now used to express the difference $(V' - V)$ in terms of the P_i, X_i and V_e, together with an expression which is of higher degree than the second in the x_i, which will be denoted by $O(x_i^3)$; this yields

$$(V' - V)V^2 = V_e \sum_{i=1}^{n} P_i X_i^2 + \tfrac{1}{2} \sum_{i=1}^{n} \sum_{j=1}^{n} a_{ij} P_i P_j (X_i + X_j)^2 + O(x_i^3) \tag{11}$$

Thus, for sufficiently small values of the x_i (that is, when the population is near the equilibrium state), we have that $V' - V > 0$; hence the mean viability increases from one generation to the next.

Using this result, we can derive, in the form given by Owen, necessary and sufficient conditions for an equilibrium to be stable. These matters will be discussed in greater detail elsewhere.

One of us (S. P. H. M.) wishes to thank Dr. A. R. G. Owen for much helpful advice and encouragement; and the Royal Commission for the Exhibition of 1851 for the award of an Overseas Science Research Scholarship.

Sexually Mature Individuals of *Xenopus laevis* from the Transplantation of Single Somatic Nuclei

A METHOD of testing the potentialities of nuclei from embryonic cells has been described by Briggs and King[1]. The method consists of transferring a nucleus from an embryonic cell into an enucleated and unfertilized egg of the same species. King and Briggs[2], who have performed their experiments on *Rana pipiens*, found that normal tadpoles resulted from eggs with transplanted nuclei in about 35 per cent of cases in which the nuclei were taken from blastulæ, but in only about 6 per cent of cases in which the nuclei were taken from late gastrula endoderm; they have not reported normal development from nuclei of post-neurulæ or later stages.

We have performed similar experiments on *Xenopus laevis*. In this species we do not enucleate the eggs, because the female pronucleus participates in the development of only a very few of the transplanted eggs; these cases can be recognized by the use of a nuclear marker[3], and are excluded from our results. The marker is introduced by taking donor nuclei from a stock of mutant individuals having only one nucleolus in all cells, as opposed to wild-type individuals in which all cells contain potentially two nucleoli. Large series of observations and measurements show no differences in the embryonic development, viability, growth-rate, and fertility between mutant individuals and their wild-type full sibs. The host eggs are taken from the wild-type stock and the female pronucleus introduces an additional nucleolar organizer when it participates in development. The origin of the nuclei in transplant-tadpoles can be interpreted with certainty by knowing the ploidy and number of nucleoli.

We have found that the great majority of normal tadpoles resulting from transferred nuclei pass through metamorphosis normally. The older frogs appear to be sexually mature males and females; the rate of growth and sexual differentiation is similar in transplant-embryos and controls. In order to test the capacity of gametogenesis in transplant-individuals, we hope shortly to breed from these. Immature oocytes were found in one transplant-frog which died two months after metamorphosis.

As with *Rana pipiens*, the proportion of normal development obtainable from transferred nuclei decreases with increasing age of the donor embryo. *Xenopus laevis* gives a smaller proportion of normal development from blastula nuclei than *Rana pipiens*, but on the other hand normal development can be obtained from much later donor stages; a pre-hatching tadpole (Nieuwkoop[4] stage 32, endoderm) was the most advanced stage of donor from which a normal individual was obtained, but this was accidentally killed shortly before metamorphosis. We have also a few frogs from nuclei which have been transferred twice (serial transfers).

Table 1 gives the numbers of metamorphosed frogs that have been obtained from different germ-layers and developmental stages of donor embryos. When transplanting endoderm nuclei from post-neurula stages care has been taken to avoid using nuclei from the region of the presumptive germ-cells.

When considering our results it is important to appreciate that the normal development of eggs with transferred nuclei may mean either that the nuclei were undifferentiated and totipotent, or that they

Table 1. METAMORPHOSED FROGS WHICH RESULTED FROM TRANSPLANTED NUCLEI

Donors			Transplants		
			Metamorphosed frogs		
Stage	Germ-layer	Total transfers	No.	Percentage of total	Percentage of normal late blastulæ
Mid and late blastula	Ectoderm	565	17	3·0	12
	Endoderm	159	12	7·5	16
Early gastrula	Ectoderm	94	7	7·5	40
	Endoderm	287	12	4·2	15
Late gastrula	Ectoderm	26	2	7·7	33
	Endoderm	185	11	5·9	16·5
Neural folds	Ectoderm	9	0	0	0 out of 1
	Mesoderm	325	4	1·2	6
	Endoderm	137	7	5·1	14
Tail bud	Endoderm	163	4	2·5	9
Muscular response	Endoderm	287	1	0·35	3
Pre-hatching tadpoles	Endoderm	357	0	0	0 out of 70
Total		2,594	77		

were differentiated, but were able to return to a totipotent state as a result of developing again in the cytoplasm of an uncleaved egg.

Our results may be summarized as follows: (1) It is possible to transplant nuclei without impairing their ability to bring about normal development. (2) Some nuclei are capable of giving normal development very shortly before the organ of which they are part becomes functional; normal development was obtained from presumptive somite nuclei nine hours before the first muscular responses. (3) Normal development results from nuclei of more advanced donor stages in *Xenopus* than in *Rana pipiens*. (4) A number of monozygotic frogs have been obtained from single donors.

It may now become possible to breed from our sexually mature individuals which have developed from single somatic nuclei, and to test their genetic qualities.

We gratefully acknowledge the technical assistance of Miss A. Jewkes. This work has been made possible by contributions from the British Empire Cancer Campaign (M. F. and T. R. E.) and the Medical Research Council (J. B. G.).

A Genetic Mechanism for 'Thread Protein' Polymorphism in Cattle

POLYMORPHISM in the 'thread proteins' of cattle sera has been described previously[1]. Four phenotypes have been found, depending on the presence or absence of one or both of a pair of threadlike zones, presumably proteins, resolved by starch-gel electrophoresis in phosphate buffer. The two zones are well separated, 'thread protein' T1 migrating more slowly than the *Sα* zone, and T2 more rapidly. Individuals with only a T1 zone (phenotype T1) are readily and consistently distinguished from individuals with only a T2 zone (phenotype T2). Samples taken from the same animal at intervals up to 18 months showed the same phenotypes as the initial samples. However, individuals with both T1 and T2 zones (phenotype T1/T2) or neither zone (phenotype T0) are not differentiated consistently, T1/T2 sometimes appearing as T0. Phenotypes T1/T2 and T0, therefore, are best considered as one phenotype (T*) in practice.

The numbers of offspring obtained from the six possible matings between the three distinguishable phenotypes are shown in Table 1. The results in Table 1 were obtained (*a*) from a large self-contained local herd of pedigree Friesians, and (*b*) from matings picked at random from Friesian herds in various parts of England. Consideration of the mating results suggested that 'thread protein' polymorphism in cattle is controlled by three autosomal genes T^A, T^B and T^O, so that zone T1 is seen in the presence of T^A and zone T2 in the presence of T^B, while T^O does not evoke the appearance of either 'thread protein'. Phenotype T1 is thus an expression of the genotypes T^A/T^A or T^A/T^O, phenotype $T2$ of the genotype T^B/T^B or T^B/T^O, while phenotype $T1$/T2 has the genotype T^A/T^B and the true phenotype T^O the genotype T^O/T^O.

Table 1. OBSERVED and EXPECTED MATING RESULTS IN BRITISH FRIESIANS

Mating (phenotypes)	No. of matings (observed/expected)	Phenotypes of offspring		
		T1 (obs./exp.)	T2 (obs./exp.)	T* (obs./exp.)
	A.	96 matings in self-contained herd		
T1 × T1	12/ 9·8	8/10·3	—	4/ 1·7
T1 × T2	14/20·4	4/ 3·3	5/ 3·3	5/ 7·4
T1 × T*	28/21·3	13/15·8	5/ 2·5	10/ 9·7
T2 × T2	5/10·7	—	4/ 4·3	1/ 0·7
T2 × T*	24/22·4	2/ 2·1	17/13·6	5/ 8·3
T* × T*	13/11·6	4/ 3·9	4/ 3·9	5/ 5·1
	B.	92 matings picked at random		
T1 × T1	7/ 5·7	6/ 5·9	—	1/ 1·1
T1 × T2	19/18·7	5/ 4·2	7/ 4·8	7/10·0
T1 × T*	18/15·7	6/10·0	2/ 1·6	10/ 6·4
T2 × T2	12/15·4	—	9/10·4	3/ 1·6
T2 × T*	30/25·8	4/ 2·6	19/17·3	7/10·3
T* × T*	6/10·8	1/ 1·8	3/ 1·8	2/ 2·4

T* = Combined phenotypes (T1/T2 + T0)

No. of matings: *A*, $\chi^2 = 7{\cdot}99$; $P > 0{\cdot}1$ (5 d.f.); *B*, $\chi^2 = 4{\cdot}25$; $P > 0{\cdot}5$ (5 d.f.).

Phenotypes of offspring: *A*, $\chi^2 = 10{\cdot}76$; $P > 0{\cdot}3$ (10 d.f.); *B*, $\chi^2 = 10{\cdot}41$; $P > 0{\cdot}3$ (10 d.f.).

The gene frequencies T^A, T^B and T^O can be calculated from the relationships $p = (T^A)^2 + 2(T^A \times T^O)$, $q = (T^B)^2 + 2(T^B \times T^O)$ and $r = (T^O)^2 + 2(T^A \times T^B)$, where p, q and r are the observed frequencies of the phenotypes T1, T2 and T*. These equations are readily solved on an electronic computer, and I am indebted to J. C. Gower, of Rothamsted, for calculating gene frequencies. The equations are satisfied by two sets of frequencies; the correct set can be chosen by examination of the mating results. From 213 animals in the local herd, p, q and r were found to be 0·320, 0·333 and 0·347 respectively, and the corresponding correct set of gene frequencies were T^A, 0·280, T^B, 0·290 and T^O, 0·430. From 184 cows, heifers and calves from the matings picked at random, p, q and r were 0·248, 0·408 and 0·343, giving T^A; 0·226; T^B, 0·338, and T^O, 0·437. Using these gene frequencies, the expected distribution of offspring in each set of data has been calculated and is shown in

Table 1. Also the expected number of each of the six possible matings has been calculated in each case and compared with the actual number found. It will be seen that the observed and expected distribution of offspring agree when tested by the χ^2 test, as do the expected and observed numbers of matings. The results presented in Table 1 therefore support the genetic mechanism proposed.

Although 'thread proteins' have been found in dogs and pigs[2], no evidence of polymorphism has been found in these zones in these animals, so far. The significance of 'thread protein' polymorphism in cattle is not clear at this stage.

There does not appear to be any correlation between the thread protein phenotypes and the six β-globulin cattle phenotypes described previously[3].

I wish to thank the Directors of Lord Rayleigh's Farms Inc., and Strutt and Parker Farms, Ltd., for permission to bleed cattle, and the veterinary officers of the Milk Marketing Board for collecting blood samples from A.I. (artificial insemination) herds.

Bones of a Vulture among the Remains of Animals sacrificed on the "Burial of Romulus" below the *Niger lapis* in the Roman Forum

In 1899 Giacomo Boni, director of the diggings in the Roman Forum, discovered, in the area of the *Comitium*, below the *Niger Lapis*, a layer containing votive bronze statuettes and sherds attributed to the sixth to seventh century B.C., and many fragments of bones, horns and teeth of *Sus*, *Ovis*, *Taurus*, *Capra* and *Canis*, obviously remains of a sacrifice[1]. This layer was enveloping the base of the '*sacellum*', a monument (including the famous archaic Latin inscription) which Giacomo Boni identified with the "*funestum locum in Comitio*" (Festus) which, following the Roman tradition, was supposed to be the burial of Romulus, or of his adoptive father Faustulus.

A recent revision of the skeletal remains of the sacrificial fauna collected in the above-mentioned layer by Giacomo Boni in 1899, and kept in Rome in the Antiquarium Forense (undertaken with the kind permission of Prof. P. Romanelli, "Soprintendente" to the Palatine and Forum), has led us to the identification of three fragments of bones of a vulture (Fig. 1). The fragments are: the distal part of a right humerus, with a small part of the diaphysis; the proximal part of a right ulna, with part of the diaphysis; another fragment of diaphysis of this latter bone. The three fragments belong to the same individual. The posterior face of the ulna shows two deep incisions, made on the fresh bone, by the knife of the sacrificer, when he cut the muscles of the fore-limb.

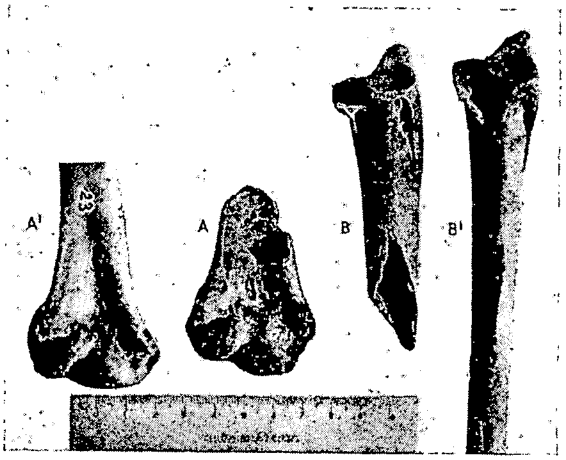

Fig. 1. *A*, distal portion of a right humerus, collected in 1899 by Giacomo Boni in the layer containing the remains of other sacrificed animals and archaic votive bronze statuettes and sherds of the sixth–seventh century B.C., underlying the *Niger lapis* in the area of the Comitium in the Roman Forum, now determined as *Vultur monachus* L. or *fulvus* Gmel. *A′*, distal portion of a right humerus of *Vultur monachus* L. (=*Aegypius monachus* (L.) Sardinia, Coll. Blanc. *B*, proximal portion of a right ulna collected in 1899 by Giacomo Boni, in the same layer as *A*, now determined as *Vultur monachus* L. or *fulvus* Gmel. *B′*, proximal portion of a right ulna of *Vultur monachus* L. (=*Aegypius monachus* (L.) Sardinia, Coll. Blanc

The morphology and the dimensions of the fragments indicate that they belong to a vulture of exceptionally large dimensions: either to the black vulture, *Vultur monachus* L.=*Aegypius monachus* (L.), or to the griffon vulture, *Vultur fulvus* Gmel.= *Gyps fulvus* Salvad. Owing to the extreme similarity of the osteological morphology and of the dimensions of these two species, and the fragmentary state of the bones examined, it has not been possible to reach a certain specific determination.

The vulture is a non-edible animal, difficult to capture, particularly in Roman times, and was protected by religious interdictions, being considered sacred to Mars and preferred to any other bird for taking omens.

Therefore the fact that a vulture was sacrificed, together with other victims, on the monument which was believed to be the burial of Romulus or Faustulus, should have an obvious relation with the story of the foundation of Rome, as reported by T. Livius and other classical authors. Romulus and Remus were said to have decided to settle their quarrel on where the new town had to be founded by watching the birds, believed to be the messengers of the gods. Remus watched from the Aventine Hill, Romulus from the Palatine. Remus is reported to have seen, first, the flight of six vultures, but Romulus is said to have seen twelve. Following Plutarch, Remus suspected a cheat, and moved towards his twin-brother. At that moment, Romulus really saw twelve vultures, and Remus had to accept the divine command revealed by the birds.

Titus Livius states that the first measure taken by Romulus as soon as he seized the power was to name twelve lictors, in remembrance of the twelve vultures which had announced to him the favour of the gods.

The tradition persisted for a long time, because, following P. Ovidius Naso, when Augustus became consul for the first time, he also saw twelve vultures, as was believed to have happened, seven centuries before, to the founder of Rome.

FORTHCOMING EVENTS

Friday, July 11

Nutrition Society (at Queen Elizabeth College (University of London), Campden Hill Road, London, W.8), at 10.15 a.m.—Symposium on "Applied Nutrition: The Human Factor in Group Feeding".

British Psychological Society, Occupational Psychology Section (in the Department of Psychology, Birkbeck College, Malet Street, London, W.C.1), at 1 p.m.—Mr. Stephen Griew: "Methodological Problems in Ageing Research in Industry".

[Saturday, July 12

British Psychological Society (at Birkbeck College, Malet Street, London, W.C.1), at 2.30 p.m.—Prof. B. Delisle Burns (McGill University): "Memory and Amnesia".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Advisory Officer (with a degree in science or agriculture, preferably with honours, and experience in investigational and advisory work) in Animal Husbandry; and an Advisory Officer (with a degree in science or agriculture, preferably with honours, and experience in investigations or research concerning poultry husbandry) in Poultry Husbandry; and an Assistant Resident Supervisor (with a degree in agriculture and a special interest in animal husbandry) for Certificate Course in Agriculture—The Secretary, North of Scotland College of Agriculture, 41½ Union Street, Aberdeen (July 10).

Metallurgist (L.I.M. or with the H.N.C. in metallurgy or physics) at the Research Laboratories, Leatherhead, Surrey, to assist in investigating unusual problems in the creep of metals used in nuclear power generation—Chief Personnel Officer, Central Electricity Generating Board, 24/30 Holborn, London, E.C.1, marking envelope "Confidential" and quoting Ref. N.167 (July 10).

Lecturer or Assistant, Grade B (with an honours degree) in Physiology or Pharmacology, for duties which include teaching and research—The Clerk to the Governors, Chelsea College of Science and Technology, Manresa Road, London, S.W.3 (July 11).

Assistant (graduate in biochemistry) in Biochemistry in the Department of Child Life and Health—The Secretary, The University, Edinburgh (July 12).

Assistant Lecturer in Organic, Inorganic or Physical Chemistry—The Registrar, The Manchester College of Science and Technology, Manchester 1 (July 12).

Assistant Lecturer (with an honours degree in psychology and additional training or experience in clinical psychology) in Clinical Psychology in the Department of Psychiatry of the Faculty of Medicine—The Registrar, The University, Manchester (July 12).

Lecturer (with a good honours degree in applied mathematics or engineering science, and preferably research experience) in Civil Engineering—The Registrar, The University, Birmingham (July 14).

Lecturer in the Postgraduate Department of Applied Mechanics—The Registrar, The University, Sheffield (July 19).

Research Assistant in Mathematical Statistics in the Department of Applied Mathematics—The Registrar, The University, Liverpool (July 19).

Research Assistant in the Unit of Biometry, for duties mainly concerned with the design and analysis of radiobiological experiments in conjunction with the Agricultural Research Council radiobiological laboratory at Grove—The Reader in Biometry, The University, 7 Keble Road, Oxford (July 19).

Research Assistants (*a*) (with a good degree in biological science or physiology, and preferably some research experience or qualification) and (*b*) (with a good degree in chemistry or biochemistry and preferably some research experience or qualification), to investigate the effects of chemical pollutants on marine organisms—The Secretary and Registrar, The University, Southampton (July 19).

Head (with high academic qualifications and considerable statistical research experience) of the Statistics Section, Rubber Research Institute of Malaya, Kuala Lumpur, Malaya, for duties which will include the design of field and laboratory experiments and the conduct of research in statistical matters relating to all branches of the Institute's work—The Secretary, London Advisory Committee for Rubber Research (Ceylon and Malaya), Commonwealth Institute, Imperial Institute Road, London, S.W.7 (July 31).

Lecturer (preferably with special qualifications in applied mathematics) in Mathematics at the University of Auckland, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, July 31).

Research Assistant in the Department of Zoology and Comparative Anatomy, to join a small group studying problems of morphogenesis—The Secretary, University College, Gower Street, London, W.C.1 (July 31).

Lecturer in Mathematical Statistics at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, August 2).

Lecturer in Chemistry at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, August 4).

Lecturer in Mathematics at the University College of Rhodesia and Nyasaland—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (August 20).

Assistant, Grade B (graduate, preferably with some previous teaching experience), for Mathematics, for duties which will involve work in degree and H.N.C. courses—The Clerk to the Governors, Mid-Essex Technical College and School of Art, Market Road, Chelmsford.

Assistant, Grade B (man), to teach theoretical and practical physics to B.Sc. General Degree students—The Clerk to the Governors, South-West Essex Technical College, Forest Road, London, E.17.

Assistant Lecturer (Grade B) in Mathematics—The Principal, Peel Park Technical College, Salford.

Assistant Physicist (with a first- or second-class honours degree and preferably previous experience) in the Radiotherapy Centre—The Medical Superintendent, St. Luke's Hospital, Guildford.

Cyclotron Radiochemist (with a good degree in chemistry and preferably some experience of radiochemistry), to take charge of the chemical aspects of radioisotope production for medical research, in collaboration with existing engineering and physics teams—The Director, Medical Research Council, Radiotherapeutic Research Unit Hammersmith Hospital, Ducane Road, London, W.12.

Lecturer in Mathematics, to teach up to B.Sc. General, Part II standard; and a Lecturer (preferably with industrial or research experience) in Chemistry, with special reference to inorganic chemistry—The Clerk to the Governors, Northern Polytechnic, Holloway London, N.7.

Lecturer or Assistant Lecturer (preferably with an interest in physiology and ecology) in Botany at Makerere College, The University College of East Africa—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1.

Lecturer or Senior Lecturer in Metallurgy in the Department of Mechanical Engineering—The Principal, Royal Technical College, Salford.

Lecturers in Mathematics—Professor D. B. DeLury, Department of Mathematics, The University, Toronto.

Physicist or Physical Chemist (with a first- or good second-class honours degree, and preferably with previous biological research experience), to work on adhesion in relation to wound dressings—The Secretary, Department of Biomechanics and Surgical Materials, Institute of Orthopædics (University of London), Royal National Orthopædic Hospital, Brockley Hill, Stanmore, Middlesex.

Research Physicists (2), to work on problems concerned with (1) X-rays and radiation dosimetry and (2) the development and application to medical research of a tritium counting apparatus—The Director, Medical Physics Unit, University of Edinburgh and South-Eastern Regional Hospital Board, 12 George Square, Edinburgh 8.

Senior Control Officer (Tsetse) (aged between 30 and 45 and with at least five years experience on tsetse control work, and able to handle large gangs of labour) with the Government of the Northern Region of Nigeria—The Crown Agents, 4 Millbank, London, S.W.1, quoting Ref. M.3A/44848/TA.

Senior Scientific Officer or Scientific Officer (with a first- or second-class honours degree in physics or engineering or equivalent, and preferably a knowledge of work involving high pressure fluids. miniature precision mechanisms, strength of materials or metal physics) in the Mechanical Engineering Research Laboratory (D.S.I.R.), Plasticity Division, East Kilbride, Glasgow, to take charge of a team working on high pressure physics—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting Ref. A.226/8A.

Senior Scientific Officers and Scientific Officers at Ministry of Supply Research and Development Establishments mainly in the southern half of England, for work in physics, electronics, electrical or mechanical engineering, applied mathematics, chemistry or metallurgy—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.182/8A.

Senior Scientific Officers (2) (with a first- or second-class honours degree in science or engineering and at least three years postgraduate experience) at the Headquarters of the Department of Scientific and Industrial Research, London, S.W.1, for scientific administrative duties—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.229/8A.

Senior Scientific/Scientific Officers (with at least a second-class honours degree in chemistry, and for one of the posts physical chemistry or applied physics experience or qualifications would be an advantage), to join a team of chemists and chemical engineers making fundamental and applied research studies in the organic chemical field, covering investigations on preparative methods of specialized materials, and physico-chemical problems arising from production and research programmes—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berkshire, quoting Ref. 187/34.

TWO WAYS OF OBTAINING DISTILLED WATER

High cost — increased transport charges — bulk storage and inconvenience.

THE OLD

THE NEW

The C.T.P. 'Deminrolit' plant above produces approximately 300 gallons hourly of distilled quality water without using heat or steam. Operating by Ion Exchange, C.T.P. 'Deminrolit' plants occupy little space, are simple to operate and ensure a demineralised water of consistent quality.

LECTURES AND COURSES

SANDWICH COURSE IN CHEMICAL TECHNOLOGY (PLASTICS)

The Department of Chemistry offers a four-year Sandwich Course in Chemical Technology (Plastics) for students possessing G.C.E. Advanced in Science subjects or equivalent qualifications. The course entails attendance for six months each year at the College, alternating with six months in industry. Students who successfully complete the course will qualify for the Associateship of the College and the Diploma in Technology. The Trustees of the Plastics Industry Education Fund have provided several scholarships for college-based students attending this course.

POSTGRADUATE DIPLOMA COURSE IN HIGH POLYMER TECHNOLOGY

The Department of Chemistry offers a one-year Diploma course for graduates in chemistry, or equivalent, in the technology, chemistry and properties of polymers. Special consideration may be given to others with lower qualifications who have had suitable experience in industry.

Further details, syllabuses and forms of application can be obtained from the Registrar, College of Technology, Birmingham. Please quote: D.

SIR JOHN CASS COLLEGE

JEWRY STREET, LONDON, E.C.3
Telephone: ROYal 3383

COURSES FOR DEGREES OF THE UNIVERSITY OF LONDON

The College prepares students by full-time and by part-time study for the Internal B.Sc. (Special) Degrees of the University of London in Chemistry, in Mathematics, and in Physics, and for the B.Sc.(Eng.) Degree in Metallurgy.

There are full-time courses for the External B.Sc. (Special) Degrees in Botany and in Zoology.

Internal B.Sc. (General) Degrees under revised regulations may also be taken by full-time, part-time, or evening courses in the above science subjects together with Geology.

Preliminary requirements are met by similar courses of intermediate standard in these subjects.

Courses, both full-time and part-time, are available for examinations of the Royal Institute of Chemistry, the Institution of Metallurgists, and the Institute of Physics.

Facilities are provided for full-time and part-time research and postgraduate work, and short courses are held on a variety of special topics.

Application forms for enrolment for the academic year 1958-59 and the College prospectus may be obtained from the Secretary.

COVENTRY TECHNICAL COLLEGE

SANDWICH COURSES FOR GRADUATE MEMBERSHIP OF THE ROYAL INSTITUTE OF CHEMISTRY

Applications invited for a two-year course for Part II G.R.I.C. Candidates should possess Part I or expect exemption with higher national certificate 1958. Studies commence October, 1958. Students can complete the course for Part II in one year by attending consecutive periods of Sandwich Course from September, 1958, until July, 1959.

Further particulars from the Principal. Applicants should write, as soon as possible, giving details of previous education and experience.

BATTERSEA COLLEGE OF TECHNOLOGY

PHYSICS DEPARTMENT

Applications are invited for enrolment for the courses in Microwave Physics beginning on September 29, 1958. Suitably qualified students may proceed to the M.Sc. degree of the University of London or the Postgraduate Diploma of the College.

For further details apply Head of Department.

OFFICIAL APPOINTMENTS

UNIVERSITY OF LIVERPOOL

Applications are invited for the post of Research Assistant in Mathematical Statistics in the Department of Applied Mathematics, at a salary within the range £500 to £700 per annum, according to qualifications and experience.

Applications, stating age, qualifications and experience, together with the names of two referees, should be received not later than July 19, 1958, by the Registrar, from whom further particulars of the conditions of appointment may be obtained.

CHELSEA COLLEGE OF SCIENCE AND TECHNOLOGY

MANRESA ROAD, LONDON, S.W.3
DEPARTMENT OF PHYSIOLOGY AND PHARMACOLOGY
Head: Mary F. Lockett, M.D.(Lond.), M.R.C.P., Ph.D.(Cantab.).

The Governing Body invite applications for the post of Lecturer or Assistant (Grade B) in Physiology or Pharmacology. Honours degree essential. Duties include teaching and research. The successful candidate will be graded as Lecturer or Assistant (Grade B) in accordance with qualifications and experience. The salary scales attached to the grades are as follows: (a) Lecturer, men, £1,200 by £30 to £1,350; women, £1,097 3s. to £1,350, plus London allowance of £36 or £48 according to age. Placing on the scale will be in accordance with previous service in a similar capacity. (b) Assistant, Grade B, men, £650 by £25 to £1,025; women, £620 to £1,025, plus additions for training (men £25 to £75; women £20 to £60). Graduate status (men £75; women £60). Honours addition (men £50; women £40) and London allowance of £36 or £48 according to age. Placing on the scale will be in accordance with previous service in a similar capacity and/or industrial experience.

Particulars and form of application from the Clerk to the Governors. Applications to be submitted by July 11, 1958.

CHIEF SCIENTIST
FOR
N.C.B. CANNOCK AREA

West Midlands Divisional Coal Board require for the post of Area Chief Scientist in their Cannock Chase Area, a man with a good degree (or equivalent) in chemistry, physics or fuel technology and having wide industrial experience.

This post entails the organization and direction of the scientific control work of the area. The control work includes air and dust analysis and the sampling and analysis of coal.

Location would be at the Area Laboratory at Cannock.

Salary within limits £1,375 to £1,850.

Applications, quoting NA, on forms obtainable from Divisional Chief Staff Officer, West Midlands Divisional Coal Board, Himley Hall, Dudley, Worcs., by July 19, 1958.

COMMONWEALTH BUREAU OF SOILS

Rothamsted Experimental Station, Harpenden, Herts. Scientific Assistant required for work in scientific information service involving abstracting and indexing. Good science degree, reading knowledge of two European languages (preferably other than French or German) and ability to write good English are essential. Knowledge of soil science and plant physiology an advantage. Salary scale £595 to £970 (bar) to £1,330 (bar) to £1,460. Qualifications, experience, National Service and age will be considered when fixing the starting salary. Two extra increments will be given on completing two years' satisfactory service for those aged 32 and under. Superannuation according to F.S.S.U.

Apply at once to Director, stating age, qualifications and experience.

APPLICATIONS ARE INVITED FOR THE position of Assistant Professor of Metallurgy, duties to commence September 1, 1958. Salary will be $6,000 per annum. Duties will include teaching and research in the field of physical metallurgy. Space and equipment facilities in the Department for teaching and research are excellent. —Applications should be addressed to the Head of the Department of Mining and Metallurgy, University of Alberta, Edmonton, Alberta, Canada, and should give personal data, details of training and experience, the names of three referees, and should be accompanied by a recent photograph. Closing date: August 1, 1958.

UNIVERSITY OF EDINBURGH AND SOUTH-EASTERN REGIONAL HOSPITAL BOARD

SCOTLAND
MEDICAL PHYSICS UNIT

Applications are invited from Physicists with experience in radiation physics and/or medical applications of radioisotope techniques for posts as Principal Grade Physicists (£1,550 to £1,850 per annum) and Senior Grade Physicist (£1,100 to £1,500 per annum). Members of the Unit apply physics to a wide range of medical problems in the hospitals in the Region and the University Faculty of Medicine, and there are excellent workshop facilities and technical assistance. The physical apparatus with which the Unit is concerned includes a 4 MeV. linear accelerator and a 2 MeV. Van de Graaff generator.

Applications should be sent, with the names of two referees, to the Secretary, South-eastern Regional Hospital Board, 11 Drumsheugh Gardens, Edinburgh, 3.

CHELSEA COLLEGE OF SCIENCE AND TECHNOLOGY

MANRESA ROAD, LONDON, S.W.3
DEPARTMENT OF CHEMISTRY

Applications are invited for the post of Lecturer with special interests in Physical-Organic Chemistry. Postgraduate research experience is essential and previous academic teaching experience is desirable. Salary scale: men, £1,200 to £1,350; women, £1,097 3s. to £1,350, plus London allowance of £36 or £48 according to age.

Further particulars may be obtained from the Clerk to the Governors, by whom applications should be received not later than July 26, 1958.

REGIUS CHAIR OF BOTANY

The Secretary of State for Scotland invites applications for the Regius Chair of Botany in the University of Edinburgh. In the past this post has been held jointly with that of the Regius Keepership of the Royal Botanic Garden, Edinburgh, but a separate appointment to the Keepership has now been made. The person appointed to the Regius Chair of Botany will be expected to take up his duties on, or as soon as possible after, October 1, 1958.

Six copies of applications, accompanied by the names of three referees, should reach the Private Secretary, St. Andrews House, Edinburgh 1, not later than July 28, 1958. A note of the terms and conditions of appointment will be supplied on request.

CENTRAL ELECTRICITY GENERATING BOARD

ASSISTANT ENGINEERS—NUCLEAR PLANT DESIGN BRANCH

ASSISTANT ENGINEERS required in Nuclear Design Section of the Nuclear Plant Design Branch at Headquarters, London, to work on problems of radiation levels in relation to Health Physics. Candidates should have a Higher National Certificate or Degree, or have other suitable technical qualifications in Physics, Applied Physics and Mathematics, or Electronics, preferably with some practical experience. Successful applicants will be given any specialized training necessary. Salaries within scales £870 to £1,045 or £1,105 to £1,315 per annum.

Application forms, obtainable from S. S. Scott, Chief Personnel Officer, 24-30 Holborn, London, E.C.1, should be completed and returned in envelopes marked "Confidential"—ref. N./173, by July 21.

ROYAL NAVAL COLLEGE

GREENWICH, LONDON, S.E.10

Posts for Senior Lecturer or Lecturer in (a) Applied Mechanics Department and (b) Physics and Electrical Engineering Department available in September, 1958, or as soon after as possible. Candidates (male) must be British and possess for post (a) first- or second-class honours degree in mechanical engineering and for post (b) honours degree or equivalent in electrical engineering; special experience in telecommunications an advantage. (Undergraduates in their final-year may apply.) Duties comprise lecturing and conducting laboratory work to degree standard. Research facilities available. Appointment as Senior Lecturer (£1,190 to £1,410), or Lecturer (£635 to £1,110), according to age, qualifications and experience; starting salary above minimum may be authorized. Post carries F.S.S.U. benefits. Single accommodation available.

Particulars and application forms from Director of Studies, R.N. College, Greenwich, S.E.10. Closing date for applications, July 18, 1958.

New John Wiley Books

ATOMIC PHYSICS AND HUMAN KNOWLEDGE

Seven Essays by

Niels Bohr

The first three essays in this book, by one of the world's greatest scientists, deal with biological and anthropological problems relating to features of wholeness displayed by living organisms and human cultures. The fourth essay is devoted to Dr. Bohr's discussions with Einstein of certain epistemological problems raised by quantum physics. The last group of essays is closely related to the first. *32s. net*

ATMOSPHERIC EXPLORATIONS

Edited by

Henry G. Houghton

(Professor of Meteorology, Massachusetts Institute of Technology)

The collected papers presented at the Benjamin Franklin Memorial Symposium of the American Academy of Arts and Sciences. They do not deal with Franklin's work or era but with the latest and most interesting developments in various fields of atmospheric exploration.

PRECISION BS INSTRUMENTS

Refractometers for Industry and Research

Our well-known standard Abbe type refractometer has a refractive index scale on glass and is read by transmitted light, thus leading to greater convenience in taking measurements and a higher degree of accuracy.

The instrument as illustrated is supplied with degree scale arc and micrometer screw reading directly to 10 seconds, corresponding to a refractive index accuracy within 0.00005. Conversion tables for use with sodium light are supplied.

Full particulars sent on application.

We shall be pleased to demonstrate these instruments and give any advice within our power, if you will call at our Works.

BROADCASTING AND TELEVISION

IN the past ten years the number of television licences in Britain has grown from less than 15,000 to nearly eight million, and the estimated number of adults aged sixteen or more in homes with television sets from 80,000 (all in the London region), which was 0·2 per cent of the total adults, to 21,850,000 or 57·9 per cent. For every person who had a television set in 1947 there are five hundred to-day, and six out of ten adults can see television in their own homes. An admirable broadsheet issued by Political and Economic Planning* sets out some of the facts behind this remarkable expansion, the characteristics of the television public and the development of commercial television and of public attitudes towards it. It attempts no critical judgments, but indicates some of the problems that accompany this rapid entry of television into the lives of millions of people, and more especially it gives a broad picture of the position of television in the economic life of the community in Britain.

Experiments in television broadcasting began in Britain in the autumn of 1929, and the world's first public television service was started by the British Broadcasting Corporation from Alexandra Palace in November 1936. When the service was closed down at the outbreak of war in 1939, there were still little more than 20,000 television receivers in Britain, and although the service was re-opened in June 1946, until 1949 it covered only the London area, and in March 1949 there were still only 127,000 licence holders. The eighteen B.B.C. transmitters now in operation cover about 98 per cent of the population, while 75 per cent are covered by the six transmitters of the Independent Television Authority, and this will be increased to 85 per cent with the opening of the Central Southern and North-East England stations later this year. By 1959–60, the Independent Television Authority hopes to have eleven stations in operation, covering about 90 per cent of the population.

Most of the television sets now in use in Britain have 14-in. or 17-in. tubes; but although screens are very much larger than they were ten years ago, the average size of a set is still smaller than in the United States. Retail sales of television receivers in Britain are estimated at 1,439,000 in 1957 at an average price of £75 18*s*., including purchase tax at 60 per cent, and about 50 per cent of retail sales during the past two years have been by hire purchase or credit transactions. Rented sets may possibly exceed half a million, and the number of new subscribers to television relay services in 1957 is put at more than 80,000.

The United Kingdom now ranks third with Canada in its ratio of persons to television receivers (6); only the United States (4) and Hawaii (5) exceed it. For Europe, Monaco (10), Belgium (45), Denmark (45), West Germany (55), Netherlands (56), U.S.S.R. (67), France (72) and Italy (78) are the only countries having ratios of less than 100. There are more television receivers in operation in the United Kingdom than in any other country except the United States, and with 55 hr. of weekly transmission the United Kingdom has double the hours of viewing of any other European country except Italy (45), France (41), Poland (39), Spain (32) and the U.S.S.R. (32), though far exceeded by the United States (133) and Canada (91). There are now more people in Britain with licences for television than for sound alone, and since 1953 the number of television licence holders has been increasing by 1·2 million each year; it is estimated that in February 1957, 36 per cent of all adults were able to receive both B.B.C. and I.T.V. transmission in their homes, and another 23 per cent B.B.C. transmission only.

The nature, as well as the size and geographical distribution of the television public, have been steadily changing since the Second World War; and while, ten years ago, in terms of social class, the upper 12 per cent had nearly half the total number of sets in use and the bottom 68 per cent only a quarter of the total, there is now little to distinguish the television public from a representative cross-section of the public in this respect, namely, one-quarter middle class and three-quarters working-class. There is also probably little to distinguish the television public from a cross-section of the public in respect of occupation and education. Households with television, however, are on average larger than those without. During the last quarter of 1957 the average evening sound audience of 3,650,000 was less than half as great as the average evening television audience of 7,400,000.

To judge of the effect of the contents of television programmes on the public would require a much more searching inquiry than P.E.P. has attempted for this broadsheet, but the comparison between the programmes of the Independent Television Authority and the British Broadcasting Corporation presents some indication that the latter has regained some ground lost initially. Nor is the effect of advertising clearer, though the growth of television advertising expenditure from some £2 million in the last quarter of 1955 to nearly £32 million in 1957 is noteworthy and is estimated at about 11 per cent of all advertising expenditure, compared with 4·5 per cent in 1956. Primarily such advertising is concerned with mass-market goods, for which the unit of purchase is small. The broadsheet concludes, however, that it is impossible to say to what extent the Press has suffered from the competition of television advertising, because the slackening in the rate of growth of total Press advertising revenues may be due to many factors unconnected with television.

---

* *Planning*, Vol. 24, No. 420 (24 March, 1958): Television in Britain. Pp. 37–68. (London: Political and Economic Planning, 1958.) 3*s*. 6*d*.

The magnitude of the economic impact of television is well summarized in the concluding section of the broadsheet. Of consumer expenditure on the provision and maintenance of television receivers, excluding licence fees, estimated at about £150 million in 1957, £109 million represents the purchase of new television receivers; £25 million the servicing of existing sets; aerials, tables, etc., £6 million; and rented sets, £12·5 million. The cost of licences to the consumer amounted to about £18 million, including £2 out of the £3 combined receiving licence which is allotted to television and an allowance for the £1 excise duty payable for only part of the year. The total £170 million is the equivalent of less than 1·3 per cent of all consumer expenditure at market prices. Television advertising expenditure, from which the independent television service is financed, approached £40 million, including production costs, and the Exchequer revenue from purchase tax on television receivers was perhaps £31·5 million. The £1 excise duty payable on television licences will yield £8 million or more in a full year, and in 1957 the Exchequer received about £15 million from the B.B.C. licence revenue.

Nevertheless, while it could be questioned whether Great Britain can afford to put into television capital expenditure of the magnitude of the post-war years, having regard to other demands for capital development, notably in transport and roads, the economic impact may well be insignificant compared with the social effects. The evidence presented in the P.E.P. broadsheet alone suggests that the standard of living in Britain is notably higher than in other European countries, or at least that the British people prefer to put expenditure on television before other expenditure that might raise standards of education, for example. It will not always be easy, in the light of this broadsheet, to counter some of the arguments which we may meet in advancing our own proposals for European Free Trade.

Apart from that, the broadsheet puts a rather different complexion on the debate regarding competitive television and the relations between broadcasting and television which preceded the establishment of the Independent Television Authority and that about the fourteen-day rule, whereby topics to be discussed in Parliament must not be raised during the previous fortnight. The broadsheet does not throw much light on the question whether television is a drug or a stimulant, and it scarcely touches the distinctive qualities of television as a medium. Nevertheless, it indicates the immense potentialities of television—and broadcasting—for informing the public mind and even moulding public opinion, and by implication the desirability of ensuring that public discussion of vital issues is as full and early and also as uninhibited as possible. It is a vital public interest that no irrelevant traditions, even of Parliament, should allow prejudices to be formed and mistaken ideas to be disseminated through an obsolete time schedule; and the replacement of the fourteen-day rule by a seven-day embargo, with most of the limitations lapsing after the second reading of a Bill recommended by a Select Committee of the House of Commons, was a sensible proposal.

It is perhaps premature to judge how far television can be a stimulant, particularly from an informative or educational point of view, without much wider inquiry into the potentialities of television as a medium. In the meantime, the evidence that it does sometimes act as a drug should induce positive action to offset secondary effects which might well be serious and could also create difficulties in the use of television for positive purposes. Published evidence as to the effect of television on social habits and hobbies does not indicate a wide difference between the habits of those owning television sets and those without, in many activities such as sport, gardening, theatre-going and card-playing: the most significant differences appear in reading, attendance at the cinema, church-going and dancing.

Certain activities have been greatly affected by the growth of television; but even so, except for reading, it could perhaps be argued that television could contribute something to offset any loss. A recent thoughtful article on the B.B.C. Third Programme and its relation to broadcasting by Dr. M. B. Counan in the *Universities Review* of February indicates the nature of such reactions and the need for forethought as to the consequences. Dr. Counan does not conceal his belief that the introduction of competitive television was an error of judgment, and urges that we should seek to secure the removal of the present B.B.C. Charter in 1962 or even to reinstate the B.B.C. monopoly. The main interest of his article, however, lies, first in its clear statement of the cultural contribution of the Third Programme, and then in its equally clear analysis of the way in which that contribution has been diminished by the failure to develop and improve it continually and to provide it with sufficient finance and time.

The latter is the vital point, for although *vis à vis* Independent television there is evidence that the B.B.C. has regained some ground, as already noted, this does not apply to sound broadcasting, and what is happening there can happen in other fields also if no effort is made to avert such consequences. As Dr. Counan observes, the influence of the B.B.C. on the cultural life of Britain must diminish even if no further changes are made. Competition with the commercial service for talent and copyright inevitably raises costs and will lead the Corporation to seek a larger licence fee. Such uncertainties, coupled with the knowledge that it is losing ground with the public, make for a lack of confidence and insecurity within the Corporation which is reflected in its programme policy.

What emerges from these preliminary inquiries is the urgent need for more objective thinking and searching, disinterested inquiry into the indirect as well as the direct effects of broadcasting, both sound and television, upon our social life and institutions. That they have immense power, both for good and for evil, over the lives and minds of men and women is widely recognized; but as yet we know relatively little about how to use that influence constructively, even in education. Meanwhile, there is danger that, apart from their destructive effect upon certain habits and institutions that make for stability and coherence in our social life, those influences may set the minds of men and women in ways which make it even more difficult to achieve the constructive possibilities. To counter that, it is the more important that the utmost use should be made of the opportunities which exist in broadcasting at present, either through the Third Programme or other programmes, of creating, possibly in co-operation with the Press and other means, an informed public opinion which is essential if policy is to be formed and action taken in fields such as defence, education, health or trade. To that end informed public discussion of current issues is a vital contribution.

THE LIFE OF DARWIN

The Autobiography of Charles Darwin, 1809–1882

Edited by Nora Barlow. Pp. 253 + 4 plates. (London: William Collins, Sons and Co., Ltd., 1958.) 16*s*. net.

LADY BARLOW keeps adding to our debt of gratitude for her untiring care in editing or de-editing the literary remains of her illustrious grandfather.

It is good to have Charles Darwin's original biographical sketch as it was written and left for the information of his children and grandchildren "with original omissions restored". His grand-daughter's notes are helpful and informative, and do not trouble or interrupt the narrative.

About half the book is, however, devoted to new material. There are two appendixes, one of eighteen pages "On Charles Darwin and his grandfather Dr. Erasmus Darwin", and one of more than fifty entitled "The Darwin–Butler Controversy". The six notes which complete the volume are of personal and bibliographical interest, and take only twenty-six pages.

The relationship between Charles Darwin's evolutionary doctrine and that of Erasmus Darwin is treated here in terms of the theories, if that is not too strong a word, held by Charles on the subject of scientific inference. I believe this point of view does less than justice to his grandfather, who wrote in the tradition of didactic poetry, and was, to the taste of his century, one of the greatest of poets. I do not understand that this fact should be ignored merely because, eighty years later, the function of poetry in contemporary literature had changed; and people like Coleridge had written spitefully.

The charge that Charles plagiarized his grandfather's work, and took credit for his ideas, was indeed nothing but a malicious falsification due, I suppose, to Samuel Butler relying on the public's lack of direct familiarity with the work of either. I could wish that Lady Barlow had given half a dozen pages in this first appendix to quotations from "The Botanic Garden" and from the "Zoonomia". The sonorous lines could be annotated from Buffon or Lucretius, lest the reader forget that Erasmus as an eighteenth century *philosophe* was expressing his appreciation of an old and richly poetic idea and not assembling the evidence for an inductive proposition. It would be apparent that Erasmus was not trying to do what his grandson later did, and this not from any lack of understanding of the proper procedure of the natural sciences.

I have, for myself, no doubt that Charles would never have undertaken the large task of marshalling the evidence for "descent with modification", which had indeed become much more impressive since Erasmus's time, without having hit upon a truly naturalistic explanation. Speculation, indeed, has an important part to play in inductive reasoning, but speculation supported by a theory which both Cuvier and Lyell had been forced to reject was to Charles Darwin a major obstacle.

R. A. FISHER

FOOD AND POPULATION

The Grassland and Fodder Resources of India

By R. O. Whyte. (Scientific Monograph No. 22.) Pp. v + 437 + 50 plates. (New Delhi: Indian Council of Agricultural Research, 1957.) Rs. 16; 36*s*.; 5 dollars.

IT has been realized for many years that the grazing and fodder resources of India are inadequate to meet the needs of the livestock population and through them the nutritional requirements of the Indian people. This volume, published by the Indian Council of Agricultural Research, reviews our present knowledge of the extent and use of these resources. The author, who is agronomist with the Food and Agriculture Organization of the United Nations, has worked in close collaboration with Indian grassland specialists for the past five years.

In India, most of the livestock is kept in the villages, and although the working animals and buffaloes are hand-fed to some extent, the cows and young stock suffer severely from malnutrition. The village grasslands are heavily over-stocked, and although they can be regenerated by controlled grazing, even then they can supply keep for only four to five months of the year. The improved herbage does not provide adequate nutrition for high-quality cattle, such as dairy cows, which require supplementary fodder rich in protein. The use of sown leys is precluded in most areas by the large and increasing human population, all the cultivable land being of necessity devoted to food and cash crops with a few annual fodder crops.

The author suggests that the most effective increase in livestock production can be obtained by controlled management of the village grasslands, based on a knowledge of their position in the ecological succession to forest, and supplemented by the conservation of fodder for the dry season, and the use of annual leguminous fodder crops.

In practice, however, these recommendations raise serious religious and social difficulties. The optimum carrying capacity of most village grasslands is far lower than the present livestock population, but the strong religious objection to killing old and surplus cattle makes the necessary reduction in numbers rather improbable in the near future. Furthermore, the small size and fragmented nature of the holdings prevent adequate provision of supplementary fodder. To maintain a family and their necessary animals requires over five acres of irrigated land, and considerably more of dryland, yet over most of India 60 per cent of the holdings are less than five acres.

These problems are social and religious rather than purely technical, and their solution depends on the informed education of the agricultural student and adviser, and through them of the farmer himself. For this purpose the present book is an admirable source of balanced and reliable information, and may well serve as a standard text-book on Indian grassland husbandry.

The standard of production, though not high, is serviceable and the price reasonable. Many of the illustrations of grassland types leave much to the imagination, and the legends on the map of soil types require a strong magnifying glass, but these are minor blemishes on a most timely and useful publication.

J. P. Cooper

PHYSIOLOGICAL ECOLOGY

The Water Relations of Terrestrial Arthropods

By Prof. E. B. Edney. (Cambridge Monographs in Experimental Biology, No. 5.) Pp. vi+109. (Cambridge: At the University Press, 1957.) 15*s*. net.

NATURALISTS have for a long time been aware that insects and many other arthropods live under conditions which often expose them to the danger of considerable desiccation. Physiologists have, in the laboratory, studied the effects of temperature and humidity on these animals, and have discovered mechanisms which enable them to survive under what would appear to be unfavourable conditions. In this book Prof. Edney has brought together the results of these laboratory investigations in such a way that ecologists will be able to find many explanations of their field observations.

Insects, and some other arthropods, are the only 'small' animals which are not either aquatic or restricted to an environment where the air is normally saturated. They are able to live under these conditions because they have a more-or-less waterproof cuticle, and because they have respiratory mechanisms which enable them to take in sufficient oxygen and lose a corresponding amount of carbon dioxide without also losing an excessive quantity of water. There are, of course, limits to the efficiency of these processes, and it is probably the need to respire which finally limits the distribution of many insects. We have known for twenty-five years that, of the water which is evaporated from insects, particularly those adapted to dry environments, practically all is lost through the respiratory spiracles, and scarcely any through the general surface of the cuticle, but a full elucidation of the nature of this cuticle, and the reasons for its remarkable properties, has taken a long time, and work is still proceeding. Prof. Edney devotes nearly a third of his text to an admirable account of our present knowledge of this subject, and he makes it as easy to understand as is possible when dealing with such an essentially complicated subject.

The second way in which these animals withstand dry conditions is by having developed excretory mechanisms which function with the minimum loss of water. Not only have they evolved means of eliminating waste nitrogen in insoluble forms (uric acid, guanine) which can be voided without any substantial loss of water, so that the urine is often practically solid, but also many have complicated mechanisms which cause the fæces also to be bone-dry. These mechanisms cannot, however, prevent considerable fluctuations in water content and in the concentration of salts and other substances in insect tissues. The ability of the insects to function normally while these changes are taking place is a further important reason for the success of the group in colonizing such a wide range of habitats. It may seem surprising to find that five pages of this short book of only 93 pages of text on terrestrial arthropods are devoted to osmotic regulation in aquatic forms, but the work described here is clearly relevant to the main argument and its inclusion is fully justified.

The ways in which arthropods gain water is also discussed. Considerable space is devoted to the interesting, and still unsolved, problem, of how some arthropods take up moisture from unsaturated air. This problem, though interesting to the physiologists, is of only minor importance in ecology, and it would perhaps have been better to have devoted more attention to the commoner methods by which water is gained. It is surprising, for example, to read that "drinking of liquid water—is confined to adults; larvæ obtaining their water with the food". The naturalists who preceded the present generation of ecologists were familiar with the way in which caterpillars would drink, and one species, the drinker caterpillar, was particularly well known in this connexion. This is, however, only a minor point, and it is very satisfactory to find the sometimes controversial question of metabolic water so clearly dealt with.

The body temperature of small animals is normally very close to that of the atmosphere, but may be higher due to insolation, and lower due to evaporation. Such cooling is relatively uncommon as it leads to desiccation, but Prof. Edney himself has shown that in woodlice it may not be unimportant. As a whole these animals supplement the physiological mechanisms by their behaviour; they can not only withstand some exposure to unfavourable conditions, they are also able to react in such a way as to find the least unfavourable positions within their environment.

Kenneth Mellanby

THERMO-ELECTRIC POWER

Semiconductor Thermoelements and Thermoelectric Cooling

By A. F. Ioffe. (Translated from the Russian.) Pp. vii+184. (London: Infosearch, Ltd., 1957.) 42*s*.; 6 dollars.

IN the early years of this century the possibility of using the thermo-electric effect to produce electrical power was explored. The idea was abandoned because of the relatively small thermo-electric powers of metal junctions. The more recent development of semi-conductors with controlled constitution and physical characteristics has caused a revival of interest in the thermo-electric generator and also in the use of the Peltier effect to provide a refrigeration unit, since semi-conductor junctions provide relatively large thermo-electric powers. In the present book Prof. A. F. Ioffe has combined two other works, one on the basic theory of thermojunctions and the other on application of thermojunctions to refrigeration. In his Institute for Semiconductors of the Soviet Academy of Sciences considerable effort has been given to the development of efficient semi-conductor thermo-elements, both for power generation and for refrigeration. It is clear from the text that the Institute is fully aware of the basic problems involved and has made progress which compares very favourably with that in Britain and the United States.

In the first part of the book, following a brief historical introduction, the author presents the fundamental theory of the various thermo-electric effects and gives special attention to the problems raised by the different statistics of degenerate and non-degenerate semi-conductors. He then gives the important criteria for efficient thermojunctions and finally derives the well-known efficiency factor which is the square of the thermo-electric power divided by the product of thermal conductivity and electrical resistivity. In giving the conditions for optimum performance the text provides a very useful discussion of the influence of such effects as phonon and impurity scattering of charge carriers. As regards experimental material, mention is made of the PbSe–PbTe and the Bi_2Te_3–Sb_2Te_3 series as sources of efficient semiconductors for thermo-electric devices.

To some extent the combination of two books produces repetition of material from the first part in the second part of the text; for example, the efficiency factor is re-presented. The second part includes an interesting summary of the experimental studies made on the selenides and tellurides mentioned above. As shown by other workers in the West, the principal problem is to prepare semi-conductors with suitable impurities so that a reduction in the thermal conductivity is obtained without a corresponding decrease in electrical conductivity.

In the last chapter of the book interesting examples of practical refrigerator units are given, while elsewhere examples of power generators (one suitable for mounting over a paraffin-lamp glass for supplying power to a radio set) are included. Although n-type PbTe–PbSe combined with p-type Sb_2Te_3 appears to be the junction used in many refrigeration units, there is a noticeable absence of specification of the junction used in the later developments where a temperature difference of 70° C. is claimed between hot and cold junctions.

On the whole, this book is a very welcome addition to the relatively sparse collected literature on semiconductor thermo-electric devices. It is lucidly written and shows an appreciation of the contemporary position in the West at the time of writing. It is to be hoped that more translations of Russian texts on solid state physics will quickly follow this one.

G. F. J. Garlick

ELECTRICAL PROPERTIES OF MATERIALS

Handbuch der Physik

Herausgegeben von S. Flügge. Band 17: Dielektrika. Pp. vi+406. 94 D.M. Band 19: Elektrische Lietungsphänomene I. Pp. vi+411. 82 D.M. Band 20: Elektrische Leitungsphänomeme II. Pp. vii+491. 112 D.M. (Berlin: Springer-Verlag, 1957.)

The three volumes in question are concerned with the theoretical physics underlying the electrical properties of materials, some of which have great technological importance. In general, the aim of the editors is to cover the theory as completely as possible, but several of the articles cater for the experimentalist who is looking for physical meaning, as well as for the pure theoretician. The bibliographies given seem up to date to 1955 or 1956; as a small point of criticism it may be mentioned that there is no consistent policy as to whether references should be given in footnotes or collected at the end of each article. Some articles are in English, some in German, and one is in French. The general index at the end of each volume is given both in German and English, with translations. The printing of the mathematical formulæ is of a luxurious standard.

Volume 17 contains three articles of about equal length. The first, on "Dielectrics", by W. Fuller Brown, covers the theory of the static dielectric constant and dielectric loss. The author gives a somewhat cumbersome text-book presentation of the subject with the emphasis on formal electrostatics. There is a short section on recent work on microwaves. The article on "Electrical Breakdown", by W. Franz, in German, contains a historical survey of the subject which is somewhat out of date on the technological side, and chapters on thermal and intrinsic breakdown. The main interest of the article lies in a discussion of the different theories of intrinsic breakdown, given with a fair amount of mathematical detail. The article on "Piezoelectricity, Electrostriction and Ferroelectricity", by P. W. Forsberg, unifies its three subjects on the basis of a treatment by tensors. This presentation leads to a certain amount of repetition, but the article reviews much recent material, and contains a wealth of beautiful illustrations.

Volume 19 is written wholly in English. J. C. Slater contributes an article on "The Electronic Structure of Solids" which introduces the reader to a subject which is the basis of a large part of Volumes 19 and 20. The article is chiefly concerned with the theory of electrons in a periodic lattice in terms of the band model, and contains sections also on cohesive energies and elastic properties and on magnetism. The author frequently includes discussions in non-mathematical terms particularly where the physical meaning of approximations is concerned. The second article, by A. N. Gerritsen, "Metallic Conductivity, Experimental Part", concentrates on work after 1945. The article covers metallic conductivity as a function of physical parameters and of crystal structure and imperfections, and contains many tables and graphs. H. Jones contributes an advanced and condensed treatment of the "Theory of Electrical and Thermal Conductivity in Metals". In particular, he gives chapters on conductivity at low temperatures and the anomalous skin effect, and he treats *Umklapp* processes more fully than usual. G. F. J. Garlick, in an article on "Photoconductivity", gives a relatively short theoretical introduction and proceeds to give a tightly packed review of post-war work, largely experimental. There is little overlap between this article and the article on semiconductors in Volume 20.

About half of Volume 20 consists of an article on "Semi-conductors" by O. Madelung, in German. This is theoretical, with the emphasis on statistical thermodynamics, but the presentation caters for the experimentalist. About 100 pages are devoted to the theory of homogeneous semi-conductors in and out of equilibrium, with the emphasis on electrical conduction, while some 30 pages deal with p–n junctions, leading logically to the theory of transistors. Surfaces and contacts are also discussed, and the author gives a summary of the experimental methods for the determination of the most important parameters of semi-conductors. Optical and magnetic properties are only touched on. The article on "Ionic Conductivity", by A. B. Lidiard, in English, is also theoretical with the emphasis on statistical thermodynamics and physical meaning. It gives an integrated picture of a subject the references to which are otherwise widely scattered. The author discusses intrinsic and structure-sensitive conductivity, and gives a section on alternating-current phenomena which is incidentally of dielectric interest. J. M. Stevels, in a comprehensive article in English, reviews the electrical properties of glass. He takes the structure as read and treats dielectric properties and electrical breakdown as well as electrical conduction. For the last article there is a change in physical imagery as well as in language, since the subject is concerned with liquids instead of solids, and the language happens to be French. E. Darmois, in an article on "Electrochemistry", gives a fairly comprehensive introduction to the theory of electrolytes and then reviews such less accessible subjects as electrocapillarity, the theory of the double layer, and electrokinetic phenomena.

CONTRIBUTION OF RADIOBIOLOGY TO GENERAL BIOLOGY

Symposium on Antibodies

Their Production and Mechanism of Action. (Given at Research Conference for Biology and Medicine of the Atomic Energy Commission. Sponsored by the Biology Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee; held at Gatlinburg, Tennessee, April 8–10, 1957. Reprinted from the *Journal of Cellular and Comparative Physiology*, Vol. 50, Supplement 1, December 1957.) Pp. x+361. (Philadelphia: The Wistar Institute of Anatomy and Biology, 1957.) n.p.

THE biological changes produced by ionizing radiations began to be studied immediately after Röntgen's discovery of X-rays, but it is only in the past fifteen years that the research effort put into radiobiology has really gained momentum. The dividend reaped has extended far beyond original expectations, and this applied research has contributed very greatly to the progress of general biology. It is a good illustration of how fundamental discoveries can spring from researches directed to a more immediate and practical end.

The annual research symposia organized by the Oak Ridge National Laboratory since 1947, on a wide range of biological topics, have played an important part in making radiation studies an integral part of contemporary biology. The subjects chosen have shown a great awareness of the trend the researches are taking and have brought together experts just at a time when the particular subject was advancing rapidly. As an example the seventh conference of the series, in 1954, may be mentioned. It dealt with genetic recombination from different aspects, and by doing so synthesized our observations on bacterial transformation and transduction and stimulated the measuring of genetic distances in molecular dimensions. This particular conference applied the Watson-Crick model of deoxyribonucleic acid on the chromosomal level, and developed new concepts which have helped considerably in the analysis of various problems of cytology and genetics. In some of the symposia, such as those on genetics, the influence of radiation formed an integral part of the topic discussed; while in others, such as those devoted to the biochemistry and biophysics of important macromolecules, radiation did not enter into the main papers at all though its relevance to the subject was brought out in the well-edited discussion.

The tenth meeting, held in April 1957, and published like all the others as a supplement to the *Journal of Cellular and Comparative Physiology*, is typical. Its subject: "Antibodies: their Production and Mechanism of Action", provided an excellent forum for the discussion of the interesting problems which arose in connexion with the application of a new method, for enhancing, and in certain instances achieving, the complete recovery of experimental animals from radiation injury. The method, first suggested by the observation of Lorenz and his collaborators in 1951, consists of the transplantation of blood-forming tissues such as the bone marrow, into animals whose hæmopoietic organs are destroyed by irradiation, and has been intensively studied in many laboratories. Progress has been rapid, particularly since 1955, when D. L. Lindsley and his colleagues (Oak Ridge) demonstrated, by using genetic markers which differentiated between host and donor, that the transplanted donor tissue took over the function of blood formation. The cytological proof that the donor cells recolonize the irradiated bone marrow was provided in the following year by J. F. Loutit and his group in Harwell. Work from several centres was summarized at the conference by C. C. Congdon and T. Makinodan of Oak Ridge, J. F. Loutit, C. E. Ford and N. A. Mitchison of Britain, and by D. W. van Bekkum and O. Vos of Holland.

The discussion of the extremely intriguing immunological consequences (for example, the co-existence of two genetically different tissues in 'chimeras'; the nature of homograft reaction; the degree of cellular adaptation; the mechanism of actively acquired tolerance) was introduced by the papers of leading immunologists and biochemists dealing with fundamental aspects of immune reactions. The induction, rate of synthesis and degradation of antibodies were discussed by W. H. Taliaferro (Chicago); the nature of the antigen-antibody reaction was described by J. F. Dixon (Pittsburgh), S. J. Singer (Yale University), R. W. Wissler and his collaborators (Chicago), and the diversity of antibodies was analysed by D. W. Talmadge (Chicago). The relationship between immunological specificity and chemical structure was the subject of E. A. Kabat's (New York) presentation. R. S. Schweet and R. D. Owen (Pasadena) discussed the nature of the change which may occur in cells responsible for antibody formation, and presented a challenging scheme postulating that the foreign antigen impinges on the nuclear deoxyribonucleic acid of the host and that the process may be considered to be similar to that of bacterial transformation; while G. D. Novelli and J. A. DeMoss (Oak Ridge) considered current concepts of protein synthesis. The symposium brought together much basic information which may enable us to apply the new method in the therapy of human leukæmias, and showed that the time has arrived for discussing the mechanisms which may be responsible for cellular variation. This formed the subject of the eleventh symposium which was held in April of this year with the title "Genetic Approaches to Cellular Variation" (see *Nature*, 181, 1706; 1958).

Of the many research centres devoted to radiation, the Biology Division of the Oak Ridge National Laboratory has for long been in the forefront not least because it realized the need to integrate this polyglot subject with the advancing fronts of biological research. Last year's symposium is further evidence to show the far-reaching influence of these conferences and the foresight of their organizer, Dr. A. Hollaender.

P. ALEXANDER

PHYSICAL CHEMISTRY AT HIGH PRESSURES

Physico-Chemical Effects of Pressure

By Dr. S. D. Hamann. Pp. ix+246. (London: Butterworths Scientific Publications; New York: Academic Press, Inc., 1957.) 42*s.*; 8.50 dollars.

THERE are several books concerned either with high-pressure technology or with the physics of high pressure, but this is the first to bridge the gap between these two subjects. Dr. S. D. Hamann, of the Commonwealth Scientific and Industrial Research Organization, Australia, has performed a valuable service in providing a concise summary of the effects of pressure in the field of physical chemistry. Although the book will be mainly of interest to physicists and chemists engaged in high-pressure research, it will also provide chemical engineers with a theoretical background to the subject.

The first part, dealing with the techniques of experimenting at high pressures, is concerned with the principles of small-scale experimental apparatus and, in particular, with those techniques, such as the generation of high transient pressures by shock waves, which have been developed during the past decade. The omission of the detailed information that is so essential in the design of high-pressure apparatus is offset by the provision of numerous references to original publications. The discussion of the effects of pressure on compressibility, phase changes, transport properties, electrolytic conduction and dielectric and optical effects deals in the main with changes brought about by pressures greater than one hundred atmospheres. In spite of this restriction, there are omissions, and some of the sections are of necessity very brief; neverthless, the treatment, which is largely theoretical, is well illustrated by carefully chosen data. The author is well known for his work on the equilibria and kinetics of chemical reactions under pressure, and the last part of the book, which contains authoritative chapters on these topics, will be of great interest to chemists. Two appendixes are provided; one containing a bibliography of Bridgman's measurements of the compressions of liquids and the other information about the effect of pressure on the freezing temperature of liquids.

Throughout the book an admirable balance between theory and experiment is maintained. Except in the section dealing with the strength of thick-walled cylinders, empiricism has been largely avoided, and an attempt has been made to give molecular models of the underlying causes of the pressure effects. In the words of the author, it is likely that time will prove some of the models wrong, but in the meanwhile they will have a use if they merely stimulate further research.

K. E. BETT

VETERINARY HANDBOOK

The Merck Veterinary Manual

A Reference Handbook of Diagnosis and Therapy for the Veterinarian. Second printing. Pp. ix+1398. (Rahway, N. J.: Merck and Co., Inc., 1957.) 7.50 dollars.

THIS publication, produced by the Merck Pharmaceutical Company of the United States of America, is intended as a reference handbook of diagnosis and treatment for the use of veterinary surgeons. Among the stimuli to its preparation was the wide and enthusiastic reception given to a similar handbook prepared for the medical profession.

While encyclopædic tomes of this type (it comprises 1,350 closely packed pages) inevitably have many weaknesses, it must be stated at once that this is a serious and, in measure, very successful attempt to provide the veterinarian with concise, authoritative and readily available information on the diagnosis and treatment of diseases of domestic animals. Emphasis, of course, has been placed on those conditions occurring in North America.

Not the least of the problems arising in the preparation of a book such as this is the matter of classification. This is greater in veterinary medicine than in human medicine because of the number and variety of species the former deals with, and the diversity of the pathological conditions encountered in them. In this manual the classification is primarily under the respective body systems, and the various diseased conditions, whether they come under the heading of general pathology or contagious disease, of each species are included. Exceptions are poultry and the non-domestic animals, which have sections to themselves. It is confusing to find diseases of cattle, sheep and pigs, horses and dogs, dealt with under the same systematic headings. One would have preferred to see each of the important species dealt with separately and the contagious diseases separated from the general ones. Surgery does not receive more than a mention when appropriate; nevertheless, those who practise in the veterinary field know that the division between clinical medicine and surgery is a purely arbitrary one and not infrequently that which may be classified as medicine necessitates surgical interference. As is the custom with books of this type, one starts with the name of the disease and then reads all about it. This, of course, is the opposite from that which prevails in the field. One commences with the animal and is primarily concerned with the clinical signs it exhibits. This is followed by a detailed examination of the various systems of its body with the view of ascertaining the site and, even more important, the extent of the disease. Its name is the last point. The task of the veterinary surgeon differs from that of the doctor in that he is chiefly governed by the economics of agriculture and thus he must accurately assess what the animal's chances of recovery are; thus prognosis is often more important than treatment. These are things that can only be taught by skilled diagnosticians working at the veterinary equivalent of the bedside and by pathologists in the post-mortem room. No book can effectively replace them.

The Merck Company are to be complimented for producing what is, of its type, an excellent book and one which, despite the criticisms made, will be found most useful to veterinary surgeons. It should be stated that it is completely free from any suggestion of advertising material.

J. G. WRIGHT

The Twice-Born

A Study of a Community of High-Caste Hindus. By Dr. G. Morris Carstairs. Pp. 343. (London: The Hogarth Press, Ltd., 1957.) 30*s.* net.

THE title of this book suggests that it is a study of the Brahmins of India and of their relations with the other superior castes. But this is not so. It is the study of a single social unit, the village of Deoli, and it is formulated from a psychological point of view, and not as a factual description. The author begins by stating his belief that it is in "the legacy of realistic imaginative writing to which the long association with Britain gave rise" that projections of Indian life as it is may best be found. Imagination is not, perhaps, to be demanded of official publications, but it should not be forgotten, in India or elsewhere, that since the issue of the first District Gazetteers in the 1860's, the Indian Government strove to publish the facts on which its actions were based. This mass of record and comment has still much to teach the serious student.

Dr. Margaret Mead in her preface describes this book as "a study of the differences in character which characterize three different castes in a remote and only recently modernized community". But caste is a Portuguese, not an Indian, word, and remote is a doubtful qualification in a sub-continent the people of which are such inveterate travellers and where accurate information frequently beats the post and Press. India has been modernized many times. Roman trade did it in the first century A.D. and the Aryans, indeed, did it before that. India has never been out of the world. Deoli had no wireless, but a decade of broadcasting, two decades of travelling cinemas, and the existence of a flourishing colloquial Press for more than a century, forbid naïvety.

The introductory chapters are curiously discursive. A party of Bhils intrudes into Chapter 8, unfortunately only to display the author's lack of preparation. For Bhils abound in these parts and the literature is adequate. The bulk of the book consists of recorded conversations with three chief informants, some of their written statements, and psychological tests.

On p. 307 it is stated that, in the word association test, Puranmal Mehta gave a delayed response to "Vagina", "Anger", "Girl", "Fæces", "Penis", and "In-laws". So should I. Oh, Seligman! Oh, Haddon! Oh, Balfour! K. DE B. CODRINGTON

Araucanian Child Life and Its Cultural Background

By Sister M. Inez Hilger. (Smithsonian Miscellaneous Collections, Vol. 133, Whole Volume.) Pp. xx + 439 + 80 plates. (Washington, D.C.: Smithsonian Institution, 1957.) n.p.

THE Araucanians of Chile and Argentina have retained their language and a good deal of their original culture after more than 400 years of contact with Europeans; much has been written about them, but little of this literature has been specifically concerned with the children. Sister Inez Hilger had much previous experience of child studies among North American Indian tribes, so she was well prepared to undertake this extensive and sympathetic account. The book contains much information about the people in general, since this is necessary to an understanding of the children. Its scope is best described by a quotation from the first sentence of the preface, "The purpose of this study is to record the ethnography . . . of the Araucanians . . . particularly their customs, beliefs and traditions in relation to the development and training of the child", and a psychological approach is expressly disclaimed, though certain psychological aspects emerged and others are implicit.

The book is clearly written and well illustrated; it maintains the high standards of the Smithsonian Institution. G. H. S. BUSHNELL

Gas Dynamics

By Klaus Oswatitsch. English version by Prof. Gustav Kuerti. (Applied Mathematics and Mechanics, Vol. 1.) Pp. xv + 610. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1956.) 12 dollars.

FIRST published in German in 1952, and now translated with only minor amendments, this excellent book on compressible fluid dynamics stands little diminished in value by the continued rapid development of its subject. Its distinction rests in the high degree of success with which Dr. Oswatitsch has related methods of analysis to physical understanding.

The first part of the book deals with both steady and time-dependent 'one-dimensional' gas flows; a wide range of topics is covered, including, for example, problems of combustion and detonation. The method of characteristics is introduced for unsteady flow. A lucid exposition of the equations of motion for flow in three dimensions follows, with more emphasis than usual on their integral forms. Attention is then narrowed to steady adiabatic inviscid flow, and the fundamentals and analytical methods of high-speed aerodynamics are surveyed in a section which occupies about half the book. Basic similarities and differences between various types of flow, and parallels with unsteady flow, are carefully brought out. The last two chapters are rather too-abbreviated sketches of the influence of viscosity and experimental methods.

This can be highly recommended as an illuminating and authoritative account, perhaps most useful to the reader who already has some acquaintance with the subject. E. P. SUTTON

Common Medicinal Plants of Darjeeling and the Sikkim Himalayas

By Dr. K. Biswas. Pp. vi + 157 + 50 plates. (Alipore: West Bengal Government Press, 1956.) Rs. 7; 11*s.* 3*d.*

THIS book, which has the benediction and recommendation of Sir Ram Nath Chopra, well known for his scientific work on drugs, opens with a chapter on "Herbal Charms" and does not seem to recover from this mixture of sorcery, magic and folklore. After the startling success of the alkaloids of *Rauwolfia serpentina* in the treatment of high blood pressure, it would be unwise to dismiss miraculous claims for some plants as baseless, but what is one to make of the following extracts? "*Drymaria cordata*: used as a medicine for dog-bites, and is also very useful as a throat paint in hay-fever, hay-asthma, diphtheria and pneumonia". "*Rhus succedanea*: juice of the leaves is said to blister the skin, used in curing indigestion and vomiting in children." Bald-pates may take hope, for *Nardostachys* "has the property of increasing growth of hairs on the head". Those who sigh for their lost youth need not despair for "*Curculigo orchioides* . . . taken with honey and cow's milk prevents weakness due to old age and bring (*sic*) in young strength and spirit in old men and women producing freshness in face and body". The book abounds in misprints and the half-tone plates are miserable. The line drawings are reasonably presentable. N. L. BOR

THE INTERNATIONAL ENCYCLOPEDIA OF PHYSICAL CHEMISTRY & CHEMICAL PHYSICS

The *Encyclopedia of Physical Chemistry and Chemical Physics,* under the editorship of Professor **E. A. Guggenheim** (Reading), Professor **D. F. Hornig** (Princeton), Professor **J. E. Mayer** (Chicago), and Dr. **F. C. Tomkins** (Imperial College), covers in an authoritative manner all aspects of the domain of science lying between chemistry and physics. The progress now being made in many branches of physical chemistry emphasizes the need for a comprehensive modern presentation of the structure of the subject. Each volume is specifically and primarily written for the physical chemist, but some volumes will be of value to chemists of all interests and to physicists and biophysicists.

The *Encyclopedia* is international in character, each topic being written by an outstanding scientist who has devoted his research to the particular subject, and the completed series will represent the status of physical chemistry at the middle of the twentieth century. It is written throughout in English, since this is the language understood, if not spoken, by the greatest number of people.

The complete *Encyclopedia* will probably comprise some one hundred volumes, arranged in about thirty groups, and the Editors have made every effort to establish continuity and coherence so that the relationship of each volume to the others is manifest. The progressive nature of physical chemistry makes it essential that publication be rapid ; consequently, the whole work is to be published in as few years as possible. In order to be of the greatest advantage to individuals, each volume is restricted to around two hundred pages, since each has a large measure of independence and may be purchased separately for study without reference to other books in the series. The *Encyclopedia* provides a modern account for the graduate and research worker, but can be read with perseverance by the undergraduate, since particular attention is given to the clear enunciation of the fundamental bases of each topic and the rigorous analysis of its development. Experimental details of an essentially practical nature are not emphasized, but a thorough background of the theoretical aspects of techniques is included so that these may be utilized and applied to the fullest extent.

The publishers will be pleased to record your interest in this project and send you when ready a fully descriptive prospectus.

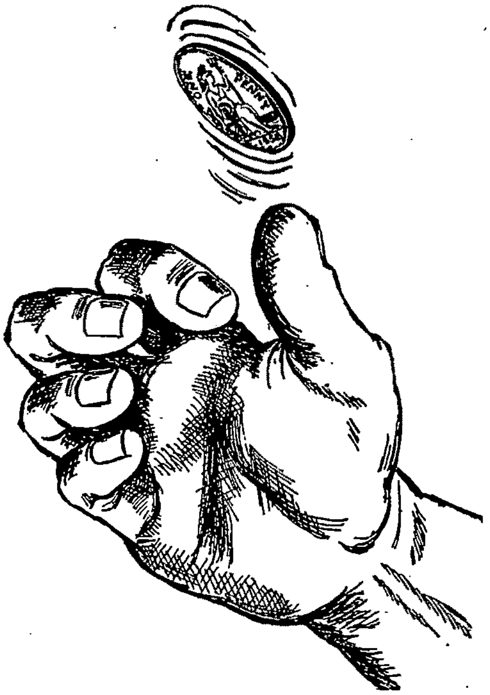
LEAK DETECTION

HEADS you find it . . .
TAILS you don't!

Don't waste time and money using inefficient and out-of-date search methods for locating leaks in vacuum systems. Leybold Vacuum Sales Ltd. offer you . . . free of cost (for the Greater London area) a leak detection service . . . fully equipped with qualified personnel and specialised instruments for locating leaks in vacuum systems. Take advantage of this service by 'phoning.

Phone GERRARD 9641

For those who prefer to have such leak detection equipment always at hand, Leybold can supply these specialised instruments.



LEYBOLD

Agents for Leybold, Germany.

VARIANCE CONTROL IN THE ANIMAL HOUSE

By Dr. J. D. BIGGERS, Dr. ANNE McLAREN and Dr. DONALD MICHIE
Royal Veterinary College, London, N.W.1

THIS article is concerned with the production of uniform laboratory animals, a subject which is of direct interest to any research worker using animals in his experiments, any organization using animals for the standardization of biological products, and also to any person concerned with the management of an animal house supplying several workers. Our interest in this problem stems from several years study on methods of controlling variation in mice, but the conclusions are applicable to work with other species.

Information in an Experiment

When we carry out an experiment we are usually interested in the value of some parameter, for example, the difference between two means, a regression coefficient or a relative potency in a biological assay. An estimate of the parameter is calculated from the observations and is subject to some uncertainty, the magnitude of which is measured by the variance of the estimate. This variance is proportional to the overall variance (the square of the standard deviation) of the responses or other biological properties being studied.

The information on a parameter is defined as the reciprocal of its variance. In practice, the amount of information that we require from an experiment is fixed by the limits of error of the estimate which we are prepared to tolerate. Thus, the more uniform we make a basic population the fewer individuals will we require to obtain the fixed amount of information. Methods of controlling the overall variance of populations are therefore of prime importance.

Causes of Variation

The variation of a group of animals, with respect to any measured character (for example, the response to a treatment), depends upon: (1) genetic factors, (2) environmental factors with persistent effects, and (3) environmental factors with transient effects. On the 'classical' model the total variance is considered as the arithmetical sum of the effects upon the animals of variation in these three categories. This view is now known to be an over-simplification. In each category we should further distinguish between those factors which increase the variance by varying from one animal to another, and those factors which act uniformly throughout the group but affect the degree to which the animals are influenced by other factors which do vary. Hitherto, attention has been focused on the varying factors. In this article we wish to direct attention chiefly to the role of uniform factors in controlling variability.

Genetic Factors

The more the individuals of a group differ in their genes, the more variable, other things being equal, will the group tend to be. The genetic differences between animals were for many years held to constitute the main cause of variation, provided that the animals were kept under uniform environmental conditions. The idea, therefore, developed that very uniform animals could be obtained by inbreeding, since in this way genetic differences between individuals can be minimized. This approach ignored the possible effects of uniform genetic factors upon variability: the genetic constitution of a population may influence the level of phenotypic variability even though all the members of the population have the same genetic constitution. In particular, it has been shown in recent years that a genetically uniform and homozygous population (an inbred strain) may be strikingly more variable than a population which is genetically equally uniform but heterozygous (the F_1 hybrid generation between two inbred strains).

The potential use of F_1 hybrids for biological assay was realized in 1946 by Mather[1], following his observation that F_1 hybrids between inbred strains of the Chinese primrose were more uniform than the parent strains. Unfortunately, this suggestion did not receive immediate attention from biological workers. In 1954, McLaren and Michie[2] and Biggers and Claringbold[3] (in ignorance of each other's and of Mather's work) reiterated this view as a result of investigations on the response of mice to 'Nembutal' narcosis and œstrogens, respectively. At that time few studies were available to indicate the generality of the phenomenon, but in the past three years a considerable literature has appeared. In 1954, Lerner[8] published his monograph, "Genetic Homeostasis", in which earlier work on the relative variability of homozygotes and heterozygotes is reviewed. The conclusion from this work was that for naturally cross-breeding species the heterozygous condition was likely to be more stable in face of environmental influences with persistent effects than the homozygous condition. In naturally inbreeding species we cannot necessarily expect the same to hold.

Table 1 provides a summary of the papers on naturally cross-breeding animal species which have appeared since Lerner's monograph. It can be seen that the relative uniformity of F_1 hybrids between inbred strains is a widespread phenomenon covering a large range of species and characters. There are two papers, however, which require comment. Grüneberg's findings[9] on a variety of anatomical characters in the mouse might suggest that only in a few cases are the F_1 hybrids more uniform than the inbreds. It must be stressed, however, that all but four characters are of the 'all-or-none' type, and that a variance calculated by the binomial theorem from the percentage incidence of such a character bears no direct relation to the variance of quantitative characters with which we are concerned. In the remaining four cases described by Grüneberg there is one instance where the F_1 is more uniform than the inbreds, two cases where the uniformity of the F_1 is about equal to that of the more uniform of the two parent strains, and one case where the inbreds are more uniform. The paper by Chai[10]

Table 1. COMPARISONS OF VARIABILITY BETWEEN INBRED STRAINS AND F_1 HYBRIDS BETWEEN THEM
The list only includes papers not found in the review by Lerner

Author	Species	Character	Result of comparison
McLaren and Michie (ref. 4)	Mouse	Duration of 'Nembutal' narcosis	Inbred more variable
McLaren and Michie (ref. 5)	Mouse	No. of lumbar vertebræ	Inbred more variable
Claringbold and Biggers (ref. 6)	Mouse	Response of the vagina to œstrogens	Inbred more variable
Yoon (ref. 7)	Mouse	Time of vaginal opening	Inbred more variable
Cuthbertson and Tomich (ref. 8) (quoted by Bacharach)	Mouse	Susceptibility to streptomycin sulphate	Inbred more variable
Grüneberg (ref. 9)	Mouse	Various morphological characters	See text
Chai (ref. 10)	Mouse	Response of seminal vesicle to testosterone	See text
Shultz (ref. 11)	Fowl	Egg shape, egg weight, shank length	Inbred more variable
Clough and Cock (ref. 12)	Fowl	Body weight	Inbred more variable
Mather (ref. 13)	*Drosophila*	Sternopleural bristle number	Inbred more variable
Thoday (ref. 14)	*Drosophila*	Sternopleural bristle number	Inbred more variable
*Maynard Smith and Maynard Smith (ref. 15)	*Drosophila*	Eclosion time	Homozygotes more variable
Reeve and Robertson (ref. 16)	*Drosophila*	Bristle number	No significant difference

* The comparison was between flies homozygous and heterozygous for a marked chromosome.

claims to show that there is no difference between the variability of F_1 hybrids and inbreds with respect to the response of the seminal vesicles to testosterone. In setting up his experiment, however, he applied the restriction that the mice should have body-weights between 9 and 12 gm. Since the weight of the seminal vesicle is likely to be highly correlated with body-weight, this restriction may have artificially brought the inbreds and F_1 hybrids being compared within the same range of variability.

The realization that F_1 hybrids were generally less variable than their inbred parents raises the question of the relative variability of inbred and random-bred animals. It seems quite possible that for some characters the greater genetic heterozygosity of random-bred animals might lead to their being phenotypically less variable than inbred animals, in spite of being genetically more variable. The use of inbred strains in biological assay and other quantitative work was stimulated in the early 1920's by King's pioneer work[17] on the growth of inbred and random-bred rats. Her observation that variability was reduced in the inbred population has unfortunately no clear-cut interpretation, since she practised selection for large body-size on the inbreds but not on the random-breds. Biggers and Claringbold[2] traced the history of this subject up to 1954 and concluded that there was no experimental proof that inbred strains were less variable than random-bred animals. The available literature is summarized in Table 2. The list is doubtless not comprehensive, but so far as we are aware it is not selected.

The results summarized in Table 2 make it clear that, unlike the comparison with F_1 hybrids, no general law can be asserted on the comparison of inbred strains with random-bred stocks. It is true that where inbred strains have been compared with unrelated random-bred stocks (Table 2, *B*), in only one instance were the inbreds less variable. But in the cases where the inbreds were compared with random-bred descendants of the same original population (Table 2, *A*) we find the inbreds to be in some instances more variable and in others less. This is not surprising, since we are dealing with the balance between two factors, both making for increased phenotypic variability—the genetic variability of the random-breds and the genetic homozygosity of the inbreds. We may expect the balance to shift from one strain or colony to another and from one character to another.

There is a practical conclusion for the experimental worker who does not wish to go to the considerable trouble and expense of maintaining inbred strains for the production of inter-strain F_1 hybrids. His most effective procedure will be to make an empirical choice from a number of random-bred colonies of that one which shows the least variability in the characters to be studied.

It is an attractive idea that one might be able to breed for uniformity, by selecting as the parents in each generation individuals falling within some restricted fraction of the total range of variation. The idea, unfortunately, receives no support from the available evidence. In fact, an *increase* of phenotypic variation has not uncommonly been encountered (see, for example, MacArthur[25], and Robertson and Reeve[26]). The possibility remains that selection from the middle fraction of the range might succeed where selection at one or other extreme fails. Falconer[27] has, however, tested this idea in *Drosophila*, and reports negative results.

It seems, then, that no purely genetical device for suppressing variability has yet been found to equal

Table 2. COMPARISONS OF VARIABILITY BETWEEN INBRED AND RANDOM-BRED ANIMALS

(*A*) Comparisons between inbred strains and the random-bred stocks from which they were derived

Author	Species	Character	Result of comparison
King (ref. 17)	Rat	Body weight	Random-bred more variable (but see text)
Morrell and Allmark (ref. 18)	Rat	Susceptibility to toxicity of neoarsphenamine	No significant difference
Rollins and Cole (ref. 19)	Rat	Response to gonadotrophins	Random-bred more variable
Kushner and Kameneva (ref. 20)	Fowl	Body size and hæmatological characters	Inbred more variable
Rasmuson (ref. 21)	*Drosophila*	Bristle number	Most inbred lines slightly less variable, some very much more variable
Reeve and Robertson (ref. 22)	*Drosophila*	Body size	Random-bred more variable

(*B*) Comparisons between inbred strains and unrelated random-bred stocks

Author	Species	Character	Result of comparison
Emmens (ref. 23)	Mouse	Vaginal cornification in response to œstrogens	Inbred more variable
McLaren and Michie (ref. 4)	Mouse	Duration of 'Nembutal' narcosis	Inbred more variable
Winton (ref. 24)	Rat	Susceptibility to toxicity of red squills	No significant difference (see Biggers and Claringbold, ref. 2)
Reeve and Robertson (ref. 22)	*Drosophila*	Body size	One inbred line more variable, one less variable

that suggested by the facts presented earlier: namely, the 'screening' of the F_1 hybrids of a number of strain combinations, or even the screening of random-bred closed colonies, in order to find a combination, or colony, with a low variance with respect to the character or response which is to be studied. A screening programme of this sort could, with advantage, be undertaken for the benefit of biological workers in general by some central organization, and we are informed by the Director that the Laboratory Animals Centre of the Medical Research Council has a project of this nature in hand, using mice. It should, however, be emphasized in the light of the next section on environmental effects that no comparison between different kinds or populations of mice can have any general validity unless the groups compared are raised under identical conditions of husbandry.

Environmental Factors

The properties of an environment, for example, temperature, humidity, composition of the diet, may vary from animal to animal during the formative period of their lives and in so doing will, of course, lead to the production of correspondingly variable animals. It is for this reason that so much effort has been expended in order to standardize conditions of, for example, temperature and diet in the breeding of laboratory animals. But again, the effect of uniform environmental factors upon variability has been virtually ignored in the past, although it has been briefly discussed by Michie[28] and by McLaren and Michie[4].

There are several reports in the literature which suggest that sub-optimal conditions may cause increased variability, even if they are uniformly sub-optimal from animal to animal. By 'sub-optimal' we mean simply conditions which deviate from those in which the given species or strain is known to be most vigorous, prolific and healthy. Increased phenotypic variability has been shown to result from both abnormally high and abnormally low temperatures in peas[29], high temperatures in *Drosophila*[14], malnutrition and reduced illumination in poultry[30] and inadequate diets in mice[31]. The work of Thoday[14] with *Drosophila* is particularly interesting since he showed that a raised temperature increased the variance of the sternopleural bristle number in both inbred strains and F_1 hybrids between them, the increase in variance being greater in the inbreds.

We have recently taken part in an experiment specifically to analyse the effect of uniform extreme climatic environments on the variability of growing mice as judged by their body-weights[32]. Table 3 shows that both the hot and the cold environments greatly increased the overall variance of the animals in both sexes. A large part of the effect was due to an increased variation among the mean values of the different litters, but a significant fraction was contributed by an increased variability among litter-mates.

Table 3. 10^5 × THE OVERALL VARIANCES OF LOG BODY-WEIGHT IN THREE DIFFERENT ENVIRONMENTS (from Ashoub *et al.*, ref. 32) Reproduced by permission of the Royal Society

Week	Females		
	Hot	Temperate	Cold
1	722	391	1,224
2	1,044	317	1,894
3	874	402	2,501
4	690	363	3,006
Week	Males		
	Hot	Temperate	Cold
1	763	458	1,093
2	801	344	1,361
3	641	518	1,629
4	575	502	1,799

The conclusion which we draw from this and the other findings summarized in this section is that the control of variability is not sufficiently ensured by establishing conditions in the animal house which act uniformly throughout the colony. These conditions must also be, so far as possible, optimal for the species or strain concerned.

Persistent Effects upon Variability: 'Constitution'

The variation which is determined genetically, together with that which is due to environmental conditions which have left a permanent imprint on the phenotype, may be termed the 'constitutional' component of the total variation. Its measurement may be used for classifying a group of animals into sub-groups which are more uniform than the original entire group as shown by subsequent tests. Biggers, Claringbold and Emmens[33] demonstrated this fact by classifying ovariectomized mice into sub-groups based on the response of the vagina to œstrone applied directly to the epithelium. The relative uniformity of the sub-groups persisted for ten weeks, at which time the experiment was discontinued. When, however, œstrone was administered systemically to the same animals by subcutaneous injection, the variability of the sub-groups was found to be as large as that of the original population. A reverse experiment showed that sub-groups more uniform than the original group could likewise be produced by tests using the subcutaneous route, but that the variability was as great as that of the original group when tested by the local intravaginal application of the hormone. Thus quite different factors of a constitutional nature may dominate the magnitude of the response according to the method of applying the stimulus.

Environmental Factors with Transient Effects

In contrast to the 'constitutional' component of variation there is finally a component due to environmental factors with transient effects. For example, two colonies of mice were used by Biggers[34] for the assay of locally applied œstrone at approximately 2-week intervals over 42 and 50 weeks, respectively. The slope of the dose-response line (in a quantal assay the slope is an inverse measure of the variance) showed considerable fluctuations in both colonies. These fluctuations must be attributed to unidentified transient environmental causes, which may or may not have been of the type which vary from one animal to the next. The next example shows that, as with genetic factors and environmental factors with persistent effects, a transient environmental factor may profoundly modify the variance of response even if it is applied uniformly throughout the group of animals. Biggers and Claringbold[35] found that the effect of injecting thyroxine was nearly to treble the variance of the response to œstrone. This effect did not persist on ceasing the injection of thyroxine. The administration of methyl-4-thiouracil approximately halved the variance of the response to œstrone, thus acting as a kind of 'uniformity drug'. In the latter case the reversibility of the effect was not tested. Earlier, Langham and Gustavson[36] had shown a similar effect in rats.

A comprehensive review of the role in variance control of uniform factors with transient effects has recently been published by Chance[37], who brings forward many new examples from his own observations. The environmental treatments implicated as having large effects on the variance of the response to a wide range of drugs in several species included temperature, the changing of cages, the size of the cage, the number of animals (female rats) in the cage (two per cage gave the least variance), and an unidentified attribute of the time of day which was found by Wilson[38] to cause changes over a thirty-fold range in the variance of the amount of histamine excreted by guinea pigs.

General Conclusions

The classical view of the causes of biological variation, whether genetic or environmental, is that these causes operate solely in so far as they vary from one member of the population of organisms to the next. We draw the inference from the material which we have reviewed that for the effective control of variation this view must be discarded. When the research worker has taken reasonable measures to ensure that a group of animals enjoy uniform circumstances of genetic background, environmental temperature, humidity and ventilation, diet, bedding, crowding, noise, routine disturbance and handling, etc., he has taken only the first step. He must next inquire whether the particular choice which he has made of genetic background, temperature, humidity, ventilation, diet, etc., is in fact the best for the given species in reducing the variance of the particular characters which he proposes to measure. It is useless to ensure a uniform level of some genetic or environmental factor if the level chosen is such as will in itself inflate the variance of the responses of the animals. There are one or two general principles which can aid his choice, as we have indicated. In general, the conditions which minimize variability seem to be those which promote the general vigour of the colony, whether we are speaking of genetic conditions (for example, heterozygosity) or environmental (for example, temperate as opposed to extreme climatic conditions). But in the end there is no substitute for trial and error. We would add a plea that workers should, if possible, publish their trials and their errors and thus put their experience at the disposal of others faced with similar problems.

THE ROYAL INSTITUTION AND THE TEACHING OF SCIENCE IN THE NINETEENTH CENTURY[*]

By E. E. IRONMONGER

Westminster Training College, London

THE part played by the Royal Institution in encouraging the teaching of science during the nineteenth century was extensive and of considerable interest.

During the course of his work as clerk of the works there in 1799, Thomas Webster had occasion to supervise the work of men employed in the building and he noticed their frequent inability to do what was required of them. "I proposed then to found a school for mechanics in the house of the Royal Institution in which they should be taught such principles of Science as would be useful in their several occupations".

After pointing out that mechanical inventions had not progressed because of the lack of scientific knowledge among working mechanics, Webster gives an outline of his scheme. There would be a preliminary and compulsory course in plane geometry, for which Rossingnol's "Elements of Geometry" was suggested as a text-book; this was to be followed by the principles of projection, for drawing and understanding plans. The students would then proceed to the principles of mechanics and hydrostatics, for which it would be necessary to procure "a little apparatus for making the most useful experiments". At this stage the men were to branch off according to their several professions: the builders to study architecture and those concerned with machinery and with engines to study higher mathematics, natural philosophy and 'chymistry'. The climax to this most strenuous course was to be a competition open to all for "a certain number to be permitted to attend the Institution gratis". In Webster's eyes, "This would be a powerful incentive to exertion and it would be an honourable testimony in their favour and could scarcely prove of any inconvenience to the Institution".

---

[*] Based on discourse delivered at the Royal Institution on May 14. A fuller version will appear in the *Proceedings of the Royal Institution*.

The scheme would start with a limited number of mechanics being sent by the proprietors of the Institution, and first attention was to be given to the instruction of bricklayers, joiners, tinners, iron-plate workers, "as these were the trades most connected with our improvements at this time". The scheme was accepted by Count Rumford, who was delighted with it, and by the Managers, after Webster had overcome the hesitations of Sir Joseph Banks: "by explaining to him how much the arts would gain by intelligent observation, I overcame a few political scruples which he had".

Some workmen were sent along and the project was launched. It is obvious, however, that from the beginning there was considerable opposition to the whole idea. Later, in 1837, Webster wrote, "I was not unacquainted with the political feelings of this time: but I did not think 'a little learning was a dangerous thing' if *judiciously bestowed,* although without due caution it might be capable of doing more harm than good. My idea was to make *good mechanics*—not to force them, like hotbed plants, out of the sphere in which they were so useful". Indeed, he pointed out the advantage of having the school in the house of the Institution, where the men "would be under the eye of the higher classes, and anything wrong would easily be put a stop to". He tried to disarm criticism by building a separate stone staircase for use by the mechanics, by constructing a gallery in the lecture theatre for those "who for obvious reasons would not like to sit down by their employers", and in other ways. All to no purpose. "But this project for improving mechanics, well intended as it was, which promised to be so useful, and which had already gained for the Institution 'golden opinions' was doomed to be crushed by the timidity (for I shall forbear to speak more harshly) of a few. I was asked rudely (by an individual I shall not name) what I meant by instructing the *lower classes* in science. I was told likewise it was resolved upon, that the plan must be dropped *as quietly as possible.* It was thought to have a dangerous political tendency. I was told that if I persisted I would become a *marked man*". By 1802 Webster had been granted leave of absence by the Managers "for the benefit of his health" and the whole project was abandoned.

Was Webster right in saying that the opposition was political? It could be. Certainly, other mechanics' institutes in different parts of England experienced similar difficulties during their early years. Other reasons have, however, been advanced. It has been said that the reason was largely financial. Alternatively, the point has been raised that the character of the Institution was to give 'fashion to science' rather than 'usefulness to science to poor and rich'.

Although the idea of a mechanics' school died almost at birth, nevertheless there was, in the early years of the Royal Institution, a certain amount of direct and continuous teaching. Both Davy and Faraday were given permission by the Managers to take private pupils in the laboratory, but the whole affair of private lectures was developed by W. T. Brande, who was appointed professor of chemistry and superintendent of the house in 1813. When appointed, he was teaching medical students at a chemical school, and permission was given to transfer these students to the Royal Institution. In 1826, a committee reported very favourably on these private classes. Brande, and later Faraday, gave these lectures in the laboratory at 8 o'clock in the morning and the lecturer received two-thirds of the subscriptions paid by the students. In its report to the Managers, the committee expressed its opinion that "these lectures have been productive of great advantage to the Royal Institution and have greatly raised its character as a school of Chemistry". The committee suggested that the lectures should be given in the theatre and that the laboratory be used for 'extended demonstrations' of the lectures. In this way more people could attend the lectures and more attention would be attracted by them. The lectures would still be given in the morning and so would not clash with the public lectures. The committee further suggested that lectures upon other subjects might be delivered upon similar terms by "Professors of eminence of different sciences" who might be invited "to give lectures to their own Pupils or classes, upon terms of admitting the Members to them gratis".

Brande was also concerned, a few years later, with an attempt to establish a school of practical chemistry at the Royal Institution. During November and December 1843, the Managers were considering a suggestion to start such a school, and Faraday and Brande had reported favourably on the scheme which would have involved special accommodation for some forty pupils. The scheme was finally turned down on the grounds of lack of space. The morning lectures continued, and among those attending were medical students from St. George's Hospital. There is evidence that some difficulty arose because the lectures were considered too technical and not sufficiently popular.

Thus, during the first half of the century many interesting attempts were made to use the facilities of the Institution for direct science teaching.

The Great Exhibition of 1851 gave a considerable impetus to scientific education and within a few years the Royal Institution had become the means of advocating the study of science. In his "Journal", for February 4, 1854, Tyndall writes: "Bence Jones is full of a project for getting seven great guns to lecture upon education". The project of the "seven great guns" soon materialized and seven lectures on science and education were delivered at the Royal Institution during 1854. Two of them are well known: William Whewell, "On the Influence of the History of Science upon Intellectual Education", and Michael Faraday's "Observations on Mental Education". A third lecture, "On the Importance of the Study of Chemistry as a Branch of Education for all Classes" by Daubeny, professor of chemistry and of botany in the University of Oxford, is interesting in several ways: first, in that it reflects the background of the time in its advocacy of scientific study based on faculty-psychology. "A study of this description . . . exercises a distinct set of faculties, just as a new gymnastic exercise calls into play a new set of muscles". Secondly, we have an interesting statement of the claim that a scientific education has advantages which a classical education has not. Here, Daubeny argues that it is desirable to train and develop at an early age "the faculty of minutely observing, of clearly apprehending and of correctly classifying the objects that present themselves". Further, after the student has left school or university he may not have an opportunity of gaining a sound knowledge of physical science, and, in any case, there are a considerable number of people who cannot stay the course in the present subjects. Finally, Daubeny expresses the desire that the universities should grant full facilities for the study of physical science.

Tyndall's own contribution to the series was "On the Importance of the Study of Physics as a Branch of Education for all Classes". He claims that the study of physics would be an advantage to all. For example, he asks, "Why should Members of Parliament be ignorant of the subjects concerning which they are called upon to legislate ? In this land of practical physics, why should they be unable to form an independent opinion upon a physical question ?" His own reactions to the lecture are interesting, and n a letter to a friend he writes : "The audience was a fine one, and included many men of eminence. Many Oxford men were present, and Faraday told me that they frowned and looked gruff at the commencement but that every man of them melted before the lecture was concluded".

This series of lectures is important in that they are evidence of an attempt to use the growing prestige of the Royal Institution to break down prejudice against science as a means of education, and to enable that subject to encroach upon the almost universal classical tradition. Some measure of their importance is seen from the discussion of them by Herbert Spencer in his famous work on education.

The story of the Royal Institution and the teaching of science during the latter half of the nineteenth century is mainly the story of the influence of individuals, and here the figure of John Tyndall overshadows all others. He had the advantage of two short periods of practical teaching at Queenwood College, where he taught physics and mathematics. In his teaching he laid stress on the practical side ; in science, he developed simple experiments for the boys to do, and in mathematics he taught practical applications of the mathematical principles. From this experience he undoubtedly learnt much that was of value to him later : the need to maintain interest when teaching and the art of devising simple but effective experiments. One of the more important contributions which he made later to the development of science teaching was the effective breaking down of prejudice by his attractive manner.

From his papers we may refer to several examples of his interest in educational questions. In 1866, Dean Farrer, then a master at Harrow, invited Tyndall to speak at the school. Tyndall's manuscripts contain the text of a speech to Harrow masters, delivered on November 15, 1866, in which his theme was the wonder and beauty of ordinary things and the need to introduce boys to the mystery enveloping the universe. "Those who imagine that science tends to destroy this mystery . . . are profoundly in error. It is science which reveals the insoluble nature of the mystery". He illustrates this by experiments dealing with the sensation of touch, with sound, light and crystallization. "All this was very wonderful to me when I first heard of it, and if properly expounded it would be very wonderful to you. No boy of intelligence and imagination could listen to such fairy tales unmoved".

Five years later he was elected a governor of Harrow School on the nomination of the Royal Society and he served in that capacity for twenty-one years, from 1871 until 1892. One can imagine his chief concern at the meetings of governors. In his "Journal", for May 21, 1884, he comments that the land for new buildings was going to cost £14,000 for foundations but that only £21 had been spent in the previous year on laboratories : "Science at Harrow is in a somewhat inanimate condition".

In another manuscript (dated June 4, 1865) entitled "Education and Physics", Tyndall tells us something of his views on the methods of teaching science. Elementary physics should be taught by experimental demonstrations. The facts of all its branches are not merely facts to be stored up in the memory but should also be copiously illustrated by experiments. Further, the relationships of such facts ought to be reasoned upon and connected, the pupils being encouraged to anticipate the connexions and then to check their anticipations by experiment. The questioning of pupils ought to go hand in hand with the performance of the experiments, and this method is preferable to that of formal lectures. The ideal way of teaching chemistry is by way of individual experiments performed by the pupils themselves. "This to my knowledge has been accomplished with great success in private schools". He recognizes, however, that the public schools may not be prepared to undertake the expense of erecting laboratories for this purpose, "though it is expected that the teacher should have a small laboratory for himself to enable him to prepare his demonstrations". He would confine attention to three sciences, elementary physics, chemistry and botany, which he prefers as "agents of discipline" to geology and physiology. Six hours a week should be devoted to science, of which three should be given to physics.

In 1859 the Department of Science and Art tried to secure better teachers of science by starting to award certificates as the result of examination. Tyndall acted as examiner for this as well as for the War Office. In an examination report, dated May 1866, he urges upon candidates and those who prepare them that "a little accurate knowledge is better than a general rambling and indistinct acquaintance with a subject". He returns to his favourite theme : "There is one great fault to be found with some . . . this is a belief that a knowledge of science means the recollection of certain phrases they have read. All teachers of science should remember that the great end of their teaching is to make their pupils *thoughtful*, prompting this thoughtfulness by making them interested and thoroughly conversant with every little step up which they are necessarily taken. The worst teachers are those who give their pupils to commit to memory or repeat to them so many dozen pages of a textbook ; the necessary result is a dislike to science".

In his written evidence submitted to the Devonshire Commission, he has several shrewd things to say as a result of his experience as an examiner. In his opinion, a great amount of sound, scientific knowledge had been diffused throughout Britain as a result of the South Kensington Examinations, although teaching appeared to be defective in practical experimentation. The amount of 'cram' was greater than it ought to be and many candidates ought not to have taken the examination. "Their incapacity must have been known to their teachers, provided the teachers themselves be not utterly incapable".

The Education Act of 1870 inaugurated the setting up of School Boards, and in his papers Tyndall has left a speech which he made just prior to the first elections to these Boards. He deals with some of the problems which are to be faced. Among these he notes, first, the problem of choosing teachers of the right quality. "The mischief done by incompetent teachers is beyond calculation". The next problem is that of text-books. "Almost every whipster imagines he can write a school book, whereas it requires the rarest faculty to write such a book." Here it may be noted that two of his own books, "On Heat" and "On Sound", were used in several public schools. He goes on to say, "The question of books will be one of the most important which the School Boards have to consider". Furthermore, the Boards will also have to determine the subjects to be taught. To the "three R's" he would add an elementary knowledge of some portion of physical science, in which he would include: the elementary facts and principles of chemistry; the nature of air and water and their functions in the human system; the facts and principles of combustion; the elementary facts of light, sound, heat, electricity and magnetism. "With the proper class-books the teacher would have no difficulty in making these things a source of unflagging interest to his boys."

In attempting to summarize the part played by the Royal Institution in the teaching of science during the nineteenth century, one may point out three stages by which the Institution's influence has developed. For nearly the whole of the first half of the century the emphasis, as we have seen, was on attempts at direct teaching. From one point of view, it may be considered that these attempts failed, and yet we may claim that not sufficient attention has been paid to them and that in many ways the Royal Institution pioneered interesting and important experiments of lasting value. The middle of the century saw the attempts to break down prejudice against science as a means of education and to enable it to encroach upon the almost universal classical tradition. Here again it is not unreasonable to say that the Royal Institution played an important part. Finally, it is hoped that sufficient has been mentioned of the influence of John Tyndall to show that, when Webster at the beginning of the century said that "the establishment of the Royal Institution ought to be considered as the commencement of a new era in the history of science in this country", he was a prophet indeed.

CONDUCTION MEASUREMENTS AT LOW TEMPERATURES

A ONE-DAY symposium on measurements of conduction at low temperatures was held by the Low Temperature Group of the Physical Society on April 11 at the Institute of Physics, and was attended by about fifty people. The committee of the Low Temperature Group, under the chairmanship of Dr. P. H. Sykes, arranged the symposium in a form similar to that of previous one-day discussions on the subjects of liquid helium and of low-temperature distillation, since it was felt that meetings of this nature make a valuable contribution towards the discussion and dissemination of recent ideas and results. Such symposia afford an opportunity, especially to younger research workers, of discussing their work informally and in much greater detail than would be possible in the more crowded and formal programme of a large-scale conference. While the time for each paper was restricted to fifteen minutes, almost as much time was allowed for discussion, so that in the course of the day it was possible to consider some thirteen contributions on several aspects of conduction measurements at low temperatures. In view of the informality of the symposium, no detailed record of the proceedings will be published.

The morning session, under the chairmanship of Dr. K. Mendelssohn (Clarendon Laboratory, Oxford), opened with a group of three papers on electrical and thermal conduction in semi-conductors.

Measurements, over the temperature range 2° K.–300° K., of the electrical conductivity and Hall effect in *n*-type indium antimonide with electron concentrations ranging from 2×10^{18} per cm.^{3} down to 5×10^{13} per cm.^{3}, were described by Dr. E. H. Putley (Royal Radar Establishment, Malvern). The ultimate purpose of the work was to estimate the purity of the parent material from the amount of electron scattering by ionized impurities at low temperatures. Because of the very small effective electron mass in indium antimonide, the electron mobilities are very high, rising to maxima as great as 700,000 cm.^{2}/V. sec. below 77° K., and the electron gas becomes degenerate at much lower concentrations than in other semi conductors so that, for example, the average relaxation times of electrons have to be obtained by integrating exactly over all energies, instead of assuming the usual formulæ for the cases of Fermi-Dirac statistics at high electron densities and of classical statistics. A theoretical calculation of the relaxation time, assuming additive inverse mean free paths for acoustical and impurity scattering, fitted the data at all temperatures, except those for impurity concentrations less than 10^{15} per cm.^{3} at temperatures below 50° K., for which the calculated conductivity exceeded the observed value by a factor of two or three. It is not yet possible to say whether this indicates a defect in the theory of impurity scattering or the presence of some additional scattering. It was pointed out by Dr. Ziman that the conventional use of the Born approximation in the theory of impurity scattering is incorrect; however, a more rigorous phase-shift calculation increases the discrepancy between the observed and calculated conductivities.

Dr. J. A. Carruthers (Clarendon Laboratory, Oxford) described measurements he had made with Dr. J. F. Cochran of the thermal conductivity of a series of *n*-type single crystals of germanium, to which Group 3 impurities had been added in concentrations ranging from 10^{14} per cm.^{3} to 10^{19} per cm.^{3}. The work was carried out between 4·2° K. and 0·2° K. as an extension to lower temperatures of previous results obtained above 2° K. In all the specimens heat was conducted by the lattice, and although in one of the pure *n*-type specimens with 10^{13} impurities per cm.^{3} phonons were scattered by the boundaries with 15 per cent specular reflexion, in all the other specimens phonons were scattered by boundaries and by an additional scattering mechanism. The phonon mean free path for this additional mechanism varied with temperature as $T^{0\cdot 8}$ in an impurity-band specimen, and varied as $T^{-1\cdot 5}$ in highly degenerate specimens, in rough agreement with a theory by Ziman on the scattering of phonons by a quasi-free-hole band with a low density of holes. For the purer specimens, the additional mean free path was approximately constant below 1° K. at values not correlated with the amount of doping impurities.

The aim of a theoretical contribution by Mr. I. C. Pyle and Dr. J. M. Ziman (Cavendish Laboratory, Cambridge) read by the former, on the scattering of phonons by a pair of impurity centres, was to explain the $T^{0\cdot 8}$ dependence on temperature of the phonon mean free path in impurity-band germanium, described in the preceding paper. Using a model proposed by Mott for lightly doped semi-conductors, which presupposes some degree of electrical compensation, the mean free path for scattering of phonons by second-order electron transitions between neighbouring pairs of impurity sites was shown to have the required decrease with temperature, and to reach a minimum value near 1° K., but the interaction was not sufficiently strong to explain the experimental results. First-order transitions, involving the complete absorption of a phonon, give a weaker interaction, but this would be increased by the fluctuations in the energies of the bound electronic states due to the random distribution of the impurities.

Electrical conductivity and galvanomagnetic effects in metals formed the subject of the last four contributions to the morning sessions.

Dr. R. W. Powell (National Physical Laboratory) described measurements, made in conjunction with Miss J. A. Nicholls and Mr. R. P. Tye, of the electrical and thermal conductivities to low temperatures of chromium, rhodium, iridium, platinum, rhenium, tungsten, cobalt, nickel, palladium, ruthenium, osmium, silver, and gold. Measurements on the specimens (which were all supplied by Johnson, Matthey and Co., Ltd., with the exception of the cobalt, which was prepared in the Metallurgy Division of the National Physical Laboratory) were also made to higher temperatures, and compared with results from the national laboratories in Canada and Australia. A study was made of the effects of heat treatment on the conducting properties of chromium in the form of a specially prepared electrodeposited tube, and it revealed the existence of an electrical resistance anomaly at about 40° C. after annealing, and of deviations from Matthiessen's rule.

In the first of the three papers on galvanomagnetic effects, Dr. R. T. Webber (U.S. Office of Naval Research) discussed measurements of the longitudinal and transverse electrical magneto-resistance of copper of extremely high purity, in fields up to 100,000 oersteds at 293°, 77°, and 4·2° K. At 4·2° K. the longitudinal magneto-resistance showed a clear-cut saturation, and all the results, except those on transverse magneto-resistance below 50,000 oersteds at 4·2° K., could be fitted to simple two-parameter analytical forms. Since the specimens were annealed polycrystalline wires of diameter greater than ten times the electron mean free path, no size effects were observed, yet the changes in resistance were smaller than those observed by previous workers on specimens in the form of strips of similar size. Kohler's rule was obeyed at 4·2° and 293° K., but not at 77° K. A similar breakdown of Kohler's rule in rhodium at 77° K., described by the next speaker, Dr. B. R. Coles (Imperial College of Science and Technology, London), is attributed to the presence at this temperature of comparable scattering by impurities and by lattice waves, each mechanism being assumed to have a relaxation time with a different lattice-symmetry and dependence on temperature, although, as pointed out by Dr. Ziman, this assumption, which is reasonable, has not been studied in detail. Rhodium also shows a reversal in sign of the Hall coefficient at high magnetic fields, as observed in other metals, and the Hall effect results can be fitted to a simple two-band model, provided one uses values of electron and hole densities which seem unrealistic in any other context. Recent work on the changes in the Hall coefficients of rhodium, palladium, and silver on alloying have shown that these are due, especially at liquid-hydrogen temperatures, not only to changes in the electronic structure, but also in part to alterations in the scattering mechanisms; and a careful interpretation of the results is necessary. In a short contribution on the theory of galvano-magnetism, Mr. F. García-Moliner (Cavendish Laboratory, Cambridge) stressed that, since the expression for the magneto-resistance contains a multiplier which involves the integration of a geometrical factor over the Fermi surface, even slight deviations of the Fermi surface from sphericity can produce large increases in the magneto-resistance. In lithium, the Fermi surface derived by Jones and Zener (with approximately 5 per cent anisotropy) gives the experimental order of magnitude for the magneto-resistance, while surfaces calculated more recently lead to results in disagreement with experiment by two orders of magnitude. The anisotropy also increases the Hall coefficients for the alkali metals by up to 3 per cent and for the noble metals by a rather larger factor sufficient to explain Dr. Coles's results on Hall coefficients.

The afternoon session, under the chairmanship of Dr. F. E. Hoare (University of Leeds), opened with three papers dealing with superconductors. Dr. L. Mackinnon (University of Leeds) reviewed previous ultrasonic conduction measurements in normal and superconducting metals, and described work in cooperation with Mr. A. Myers on absorption of ultrasound in tantalum and mercury. Different absorptions in superconducting and normal tantalum were observed, but the specimen used was not pure enough to show a large effect. Although in mercury, where a very pure specimen is easier to obtain, the effect is much more noticeable, the attenuation of longitudinal waves in the normal metal shows a peculiar behaviour on application of a transverse field. Further experiments on this effect are in progress; an earlier specimen has shown a good, if fortuitous, correlation with recent theories on the energy gap.

Measurements on the thermal conductivity of superconducting lead at temperatures close to 1° K., at which lattice conduction predominates, were described by Dr. H. Montgomery (Atomic Energy Research Establishment, Harwell). It was found that small percentages of alloying material cause only Rayleigh scattering of the phonons, but that plastic deformation greatly reduces the lattice conduction, and it appears that dislocations are distributed at random in annealed material, whereas in strained material they are assembled in mosaic walls. To overcome the effects of self-annealing at room temperature, measurements on lead alloys strained at 4° K. and on a harder metal, niobium, strained at room temperature, were made by Mr. P. M. Rowell (Clarendon Laboratory, Oxford). The thermal resistivity due to initially straining a niobium specimen varies as the 0·8th power of the strain, and as the niobium and lead alloy specimens are strained progressively, the extra thermal resistivity varies with temperature as $T^{-2\cdot 0}$, as expected from the work of Klemens and of van Bueren on dislocations. Pure lead specimens do not show a similar behaviour.

The last three papers dealt with various aspects of scattering by impurities.

The electrical resistance of molybdenum and tungsten specimens irradiated at 77° K. has been measured at helium temperatures by Mr. M. W. Thompson (Atomic Energy Research Establishment, Harwell). Increases in resistance are found to recover after thermal annealing, and activation energies have been determined for the principal recovery processes; these occur at − 170° C. and + 150° C. in molybdenum, and at − 80° C. and + 320° C. in tungsten. It was suggested that recovery in the lower temperature-ranges is due to interstitial atoms being released from traps, whereas that at higher temperatures is due to migration of vacancies. A resistance minimum observed in molybdenum near 10° K. became less pronounced after irradiation and recovered its original form only after annealing at 1,500° C. Miss J. N. Lomer (Clarendon Laboratory, Oxford) described work carried out with Dr. H. M. Rosenberg on a method for determining dislocation densities in α-brass by measurements of lattice thermal conductivity at liquid-helium temperatures. It was found that the dislocation densities introduced by strain are independent of the percentage of zinc alloyed, but depend only on whether the deformation is by single or multiple slip. The dislocation densities reach saturation at strains corresponding to the flattening-out of the stress-strain curves, and these saturation values increase with increasing zinc content. The method is useful for fatigued materials, where the dislocation densities for cyclic stress are found to be the same as for the equivalent tensile stress.

Experiments to determine the thermal resistance due to isotopes in crystals of isotopically enriched lithium fluoride were described by Dr. R. Berman (Clarendon Laboratory, Oxford). The scattering of single phonons can be calculated with reasonable certainty, but it is difficult to deduce the resultant thermal resistance, because the amount of mutual phonon interaction is uncertain. For low concentrations of either lithium-6 or lithium-7 the resistance is two to three times less than for the limit of very strong mutual phonon interactions; it is hoped to measure crystals with high concentrations of isotopes to determine the thermal resistance when mutual interactions are relatively weak. J. A. Carruthers

NEWS and VIEWS

National Physical Laboratory : Dr. J. A. Pople

Dr. John Anthony Pople has been appointed superintendent of the newly created Basic Physics Division at the National Physical Laboratory. Dr. Pople, who was born in 1925, graduated from Trinity College, Cambridge, being a 'wrangler' in the Mathematical Tripos. After a short period with the Bristol Aeroplane Co., he returned to Cambridge as a research student under the late Sir John Lennard-Jones. His work in this field led to the award of a Smith Prize in 1950 and election to a fellowship at Trinity College in 1951. Since 1954 he has been a lecturer in mathematics at Cambridge. This year he has been awarded the Marlow Medal of the Faraday Society. Dr. Pople has made theoretical contributions to a number of branches of molecular physics. Working with Lennard-Jones, he took part in the general development of the molecular orbital description of the electronic structure of molecules and has since been concerned with its application to specific problems. In addition, he has worked on the statistical mechanical theory of thermodynamic, dielectric and transport properties of liquids and gases. More recently, he has spent some time in the laboratories of the National Research Council of Canada at Ottawa, working on the interpretation of nuclear magnetic resonance spectra. The present physics programme of the National Physical Laboratory has its origin in the Laboratory's responsibility for measurement of physical constants and has a strong classical flavour; measurement of high pressures, ultrasonics, thermal conductivity and strength of materials are typical items. New fields to which consideration is being given are nuclear magnetics resonance, high polymer physics, and other aspects of molecular physics, including biophysics.

Chemistry at Khartoum : Prof. J. Miller

Dr. Joseph Miller, who is at present reader in physical organic chemistry in the University of Western Australia, has been appointed to the chair of chemistry in the University of Khartoum. Prof. Miller is a graduate of University College, London, where he obtained first-class honours in chemistry in 1939. On the outbreak of war, he entered the armed services and obtained a commission in the Royal Engineers. He served throughout the War in chemical warfare units and in various theatres in the Mediterranean, and was discharged in 1946 with the rank of captain. He returned to University College and completed his doctorate in 1948 with a thesis dealing with the hydrolysis of oxime esters. He then joined the staff of the University of Western Australia, where he built up an active research school in physical organic chemistry, the work of the group being directed mainly to the investigation of nucleophilic substitution in aromatic compounds. During 1954, he visited the United States as a Fulbright Visiting Lecturer and spent extensive periods at both the University of California and the University of South Carolina as well as visiting a number of other centres. Prof. Miller, who is married and has three children, proposes to take up his duties at Khartoum at the beginning of the academic year this month.

Brewing Industry Research Foundation : Dr. W. P. K. Findlay

Dr. W. P. K. Findlay has been appointed assistant director of the Brewing Industry Research Foundation, Nutfield, Surrey, in succession to Dr. A. H. Cook, who has recently been appointed director (see *Nature*, 181, 810 ; 1958). Dr. Findlay graduated in botany at the Imperial College of Science and Technology, London, and afterwards gained an Empire Cotton Growing Corporation Fellowship for research at Cambridge and at the Imperial College of Tropical Agriculture, Trinidad. In 1927, he was appointed mycologist at the Forest Products Research Laboratory of the Department of Scientific and Industrial Research, where he now holds the post of senior principal scientific officer. Dr. Findlay has been president of the British Mycological Society, chairman of the Biological Council and president of the Association of Applied Biologists.

Darwin–Wallace Centenary

The Royal Society, in conjunction with the Linnean and Geological Societies, is arranging a conversazione to be held on July 15 to mark the centenary of the reading before the Linnean Society of the paper "On the Tendency of Species to form Varieties", by Charles Darwin and Alfred Russel Wallace. A joint committee of the three Societies has chosen a number of exhibits, some of purely historical interest, others illustrating current research in fields in which Darwin and Wallace worked.

On the following day, July 16, the fifteenth International Zoological Congress opens in London under the presidency of Sir Gavin de Beer, director of the British Museum (Natural History). Sir Julian Huxley will deliver the Darwin–Wallace Memorial Lecture in the Royal Albert Hall during the inaugural meeting of the Congress of Zoology, at 11.30 a.m. on that day ; this Lecture will be open to the public, and seats (2*s.* 6*d.*) are available at the Box Office of the Royal Albert Hall. The record number of nearly two thousand members from fifty-eight countries are attending the Congress, the main theme of which will this year be evolution. All the papers have been printed beforehand so that they can be distributed at the sessions where they are read, and they will be issued, together with records of the discussions, as the Proceedings of the Congress.

Science in the Civil Service

In his chairman's address to the thirteenth annual delegate conference of the Institution of Professional Civil Servants at Hastings on May 19, Mr. E. Hewlett stressed the adverse effect on the structure of the whole of the professional scientific and technical Civil Service of the depression of status of higher grade professional and scientific staff which characterized the Service. Referring as example to the recent appointment of a Comptroller of the Patent Office from the administrative class without qualification in either science or law, Mr. Hewlett said that in 1925 a memorial was addressed to the Board of Trade which, after directing attention to the increasing importance of the Patent Office to our scientific industries, continued : "In modern industry, scientific invention exerts an overwhelming influence, inasmuch as only by invention can new industries be created and dying industries revived. We therefore . . . direct your attention to the desirability of ensuring that the Comptroller of the Patent Office, in addition to possessing the requisite legal knowledge, should, by education and training, be familiar with scientific discovery and development as applicable to manufacture". This statement, said Mr. Hewlett, has even more force to-day, but although the battle had seemed to be won in 1925 when the Institution's journal commented that the fundamental principle that professional, scientific or technical work should be controlled by properly qualified officers was gaining wider acceptance, it seems that the success once achieved might be snatched or whittled away in a few years time.

A motion before the Conference, submitted by the Patent Office Examining Staffs Branch, viewed "with the utmost alarm the continuing encroachment into posts requiring professional qualifications and experience of officers qualified only in an administrative capacity" and registered "its full support of all actions of the National Executive Committee to arrest this practice". The general secretary, Mr. Stanley Mayne, in a wide-ranging speech on May 19, cited numerous other instances of Government failure to deal effectively with scientific matters, and to provide the conditions which would attract to the Civil Service sufficient men and women of the highest scientific and technical qualifications. Public service, said Mr. Mayne, itself is bound to be much of its own reward, but the treatment of some groups was so discouraging as to be a national danger.

Agricultural Research

Replying to an inquiry in the House of Commons on June 16 regarding progress in research into the prevention of losses among lambs from Nematodirus, the Minister of Agriculture, Fisheries and Food, Mr. J. Hare, representing the Lord President of the Council, said that much research bearing directly and indirectly on Nematodirus was in progress all over the world. Fundamental research on the life-history and epidemiology of the parasite was proceeding at several agricultural research institutes in Britain and work on new anthelmintics was being carried out by the pharmaceutical industry. It was too early to assess the bearing of this work in reducing losses from Nematodirus, but Mr. Hare agreed this was an important disease among hill sheep and said he would see that the scale of research devoted to it was adequate.

On June 16, and again on June 19, Mr. Hare was questioned about the work of the Farm Buildings Research Committee. This Committee, set up by the Agricultural Research Council in June 1957, had met three times. A special unit had been established by the Research Council to survey existing buildings and the immediate requirements of farmers. Reports had also been called for from experts in animal physiology, pest infestation and agricultural machinery. In collecting this information the Council was co-operating closely with the Agricultural Land Service, but Mr. Hare said that it would be some time before the results of these inquiries enabled the Committee to formulate research requirements and recommendations to meet them. Two members of the Committee were members of the Royal Institute of British Architects and consultation with the Institute would be arranged when it was likely to be of value.

Aircraft Industry

Replying to questions in the House of Commons on June 16, the Minister of Supply, Mr. Aubrey

Jones, said that about 250,000 persons were employed in all branches of the aircraft industry and on present orders and inquiries it would be about 150,000 in five years time. He had recommended the industry to pursue a policy of diversification, so that problems arising from the contraction of orders for aircraft would be mitigated. His Department was not at present giving financial support to an Earth satellite programme but there were constant consultations with the Lord President of the Council and the Royal Society as to the scientific value of such a programme.

Committee on the Composition of Milk

THE committee on the Composition of Milk, set up in May by the Ministry of Agriculture, Fisheries and Food, held its first meeting on June 27, and decided to invite written evidence from any interested persons or associations. The committee's terms of reference, which include all aspects of milk composition at all stages of production and distribution, are as follows: "To consider the composition of milk sold off farms in the United Kingdom from the standpoint both of human nutrition and animal husbandry, and to recommend any legislative or other changes that may be desirable". The members of the committee are: Dr. J. W. Cook (chairman), Prof. R. G. Baskett, Mr. S. Clifford, Miss R. L. Cohen, Prof. E. L. Crossley, Dr. D. P. Cuthbertson, Dr. P. R. Evans, Mr. G. N. Gould, Prof. W. Holmes, Dr. H. E. Magee, Prof. B. S. Platt, Dr. A. Robertson, Dr. R. Waite, Mr. H. L. Webb and Dr. E. C. Wood. Evidence should be sent not later than October 31 to the Joint Secretaries, Ministry of Agriculture, Fisheries and Food, Great Westminster House (Room 280), Horseferry Road, London, S.W.1.

Causation of Cancer

AN introduction by Prof. A. Haddow, in which he pays tribute to Sir Ernest Kennaway's work, and twenty summaries of work in the different fields of cancer research have recently been published in "Causation of Cancer" (*The British Medical Bulletin*, 14, No. 2; May 1958. Edited by Prof. E. Boyland. Pp. 73–196+4 plates. London: British Council, 1958. 25*s*. net). Haddow summarizes the vast field of the mode of action of chemical carcinogens, and L. A. Elson discusses some dynamic aspects of chemical carcinogens. Cocarcinogenesis is dealt with by M. H. Salaman, and experiments indicating the irreversibility of the changes in the epidermal cell of the mouse after application of carcinogen are described by J. W. Orr, who, from a histologist's point of view, favours the concept of tumourigenesis as being the result of colonies of six or seven adjacent mutated cells. Avian carcinogenesis is reviewed by P. R. Peacock, who directs attention to McGowan's finding of weasel bites as a possible clue to the etiology of fowl tumours. Peacock's observation that cauterization 2–9 days after inoculation with virus will produce tumours anywhere in the fowl seems to offer possibilities of a quantitative estimation of viral antibody formation. F. Bielschowsky and E. S. Horning review the aspects of endocrine carcinogenesis, and H. N. Green describes his immunological theory of cancer. The present knowledge of possible exogenous factors in the causation of lung cancer is summarized by the late Sir Ernest Kennaway and A. J. Lindsay. There are papers by G. M. Bonser, D. B. Clayson and J. W. Jull on chemically induced bladder tumours, the biochemistry of bladder cancer by E. Boyland, on chemically induced liver tumours by J. M. Barnes and R. Schoental, radiation-induced skin tumours by Glücksmann, and radiation-induced tumours of the thyroid gland by I. Doniach. Occupational carcinogenesis is reviewed by M. W. Goldblatt, and A. L. Walpole and M. H. C. Williams describe the carcinogenic hazards encountered in the aromatic amine industry, and the work on the carcinogenicity of different fractions of mineral oil is reported by J. W. Cook, W. Carruthers and D. L. Woodhouse. I. Hieger presents data on the extremely important question of the carcinogenicity of cholesterol. Unfortunately, the table presented seems to indicate that the desiderata for biological examination of carcinogenic substances as described by E. Boyland earlier in the volume have not been fulfilled. W. M. Court-Brown summarizes work on the incidence of leukæmia and radiation, and R. H. Mole deals with the development of radiation leukæmias in animals and the dose-response relationship in radiation carcinogenesis. Many of the summaries contain data and points of view which have been published earlier and in some instances the limited space available has had a severely restricting effect upon the selection of relevant data.

Science Education in South Africa

THE Cape Section of the South African Association for the Advancement of Science has recently conducted experiments on methods for the popularizing of science for the general public and on improvement of science education in schools. First, its Subcommittee on Science Education suggested to the Department of Extra-Mural Studies in the University of Cape Town that it should hold a refresher course for science teachers as one of its vacation courses. In July 1957 courses covering the physical and biological sciences were attended by 160 science teachers and inspectors. Further courses will be held annually, and other South African universities in each of the four provinces are now following suit and holding similar refresher courses. Secondly, in collaboration with the Royal Society of South Africa and the Adult Education section of the Department of Education, Arts and Science, the Association organized a science exhibition in Cape Town in March of this year. Held in the historic eighteenth century Old Supreme Court, twenty-two exhibits on various aspects of scientific research in Cape Town were displayed by some departments of the University as well as the South African Museum, the Royal Observatory and numerous industrial and medical research institutions, and amateur scientists. The main purpose was to present to the general public current research problems in a simple manner, so as to offer the layman the opportunity of becoming more knowledgeable about science and the role of science in society. The newspapers gave full coverage in feature articles and editorials, indicating clearly that such knowledge has become almost a civic duty for an informed democracy in the present age; radio broadcasts were also given along similar lines. All local schools were invited to send senior pupils so as to arouse interest in the young in taking up science as a career. During the five-day period that the exhibition was open, 5,000 people of all ages and races attended. Simultaneously, a series of science films were shown by the Association. As an experiment it was highly successful, and the Association is now planning a similar exhibition on a national scale.

Reports on Radiation Chemistry

THE United Kingdom Atomic Energy Authority Research Group has recently published selected abstracts of unclassified reports in the field of radiation chemistry and a bibliography of the published literature up to February 1957, compiled by R. W. Clarke (pp. iv+209. A.E.R.E. *C/R* 1575. Parts 1–6. Supplement 1. London: H.M. Stationery Office, 1957. 28*s.* net). This publication contains 877 references and is divided into six sections, dealing with water and aqueous inorganic systems; organic compounds; gaseous systems; solid systems; biochemistry and radiobiology; and miscellaneous, including colloids, applications of radiation and general reviews. Author and subject indexes are provided. In the individual sections, report abstracts are given first, followed by annotated 'open literature' references. The report references are arranged alphabetically and serially by report reference number, and the other references by author. Recent declassified American reports are included.

Guide to Literature on Atomic Energy

A HANDY booklet entitled "Guide to U.K.A.E.A. Documents", edited by J. Roland Smith (pp. 20. London: United Kingdom Atomic Energy Authority, 1958), provides a general description of the form in which information concerning the U.K. Atomic Energy Authority is published with special reference to its own publications and of their availability to the public. After explaining that the Authority consists of three Groups—Industrial, Research and Weapons Groups—and a London Office and that scientific and technical information is issued by the Groups independently, the Guide details how unclassified information is published and where unclassified documents may be obtained or consulted. Current reports are listed every month in the "U.K.A.E.A. List of Publications Available to the Public" which the Authority's library at Harwell compiles and issues free of charge. Cumulative lists are also published. Classified documents cannot be made generally available, but in certain circumstances may be accessible to industry, research and government organizations. Finally, the Guide lists and explains the various serial codes and numbering systems used by the Authority for reference to documents and reports. This will be of great value to librarians and cataloguers. For material of more general interest, for example, news of the Authority's activities, lectures delivered by members of the staffs, lists of patents, etc., attention is directed to the monthly bulletin, *Atom*, which is issued by the Director of Public Relations from the London Office (11 Charles Street, S.W.1).

The African Pygmies

A PAPER entitled "The African Pygmies", by Prof. R. Ruggles Gates, has recently appeared in *Acta Geneticae, Medicae et Gemellologiae* (7, 159; 1958). A detailed discussion of the early literature is given with observations on skin colour, blood groups, and skull and skeletal measurements. It concludes with theories on the origin and relationships of the African Pygmy. The early literature shows that Pygmies occupied a much wider area than at present, which included the Cameroons, Sierra Leone and probably Liberia. Accounts are given of early as well as later European contacts with the tribes. The Pygmies are of ancient origin, with mahogany skin and hairy body. The Negroes have since acquired a black skin by mutation and their bodies have become hairless. The common ancestor of both is thought to be a tall mahogany-skinned race with a hairy body, but this race may now be extinct. The dwarfing of the Pygmy is the result of a single gene mutation of the achondroplastic type. Racial mixture with the Negroes is considered. The Pygmies hunt in the forest, supplying meat to their Negro overlords, who in turn give the Pygmies bananas, this being a symbiotic relationship. However, this is fairly recent, for prior to the introduction of the banana the Pygmies probably fed themselves. Forest Negroes frequently take a Pygmy wife and the children become 'Negroes', but the reverse does not occur; consequently, the Pygmies remain pure except for occasional unofficial mixing. The F_1 hybrids are intermediate in stature and backcross to the Negroes, so becoming absorbed. Measurements show that the Pygmy skull is frequently little smaller than that of the Negro. The ranges apparently overlap, although some Pygmy skulls are very small. The Pygmy skull is very primitive and characteristic, and the Pygmy teeth and jaws are the worst in the human race. This probably has a nutritional basis.

Institute of Physics

AT the annual general meeting of the Institute of Physics held in London on July 1, Sir George Thomson (master of Corpus Christi College, Cambridge) was elected president. Dr. R. W. Sillars was elected a vice-president; Dr. J. Taylor, honorary treasurer; and Prof. F. A. Vick, honorary secretary. The two new ordinary members of the Board elected were Dr. A. C. Menzies and Dr. J. Topping. Sir Lawrence Bragg (resident professor and director of the Davy Faraday Laboratory of the Royal Institution) was elected to honorary fellowship in recognition of his eminent work and valuable contributions to knowledge in the field of physics.

Royal Meteorological Society: Officers for 1958–59

THE following were recently elected to office in the Royal Meteorological Society: *President*, Prof. P. A. Sheppard; *Vice-Presidents*, Dr. A. W. Brewer, Dr. H. L. Penman, Dr. C. H. B. Priestley and Dr. R. C. Sutcliffe; *Vice-President for Canada*, Mr. R. C. Graham; *Vice-President for Scotland*, Mr. J. R. Atkinson; *Treasurer*, Mr. B. C. V. Oddie; *Secretaries*, Mr. P. J. Meade, Dr. R. S. Scorer, Mr. J. S. Sawyer (*Editor*), Dr. A. G. Forsdyke (*Librarian*).

All-India Congress of Zoology

THE Zoological Society of India is organizing the first All-India Congress of Zoology at Calcutta during October 31–November 6. It is the first time that an attempt has been made in India to hold such a conference and to bring together all the zoologists of the country. A number of delegates from foreign countries are expected to attend. The last date for submission of papers to be read before the Congress is August 15. Further information can be obtained from Dr. B. S. Chauhan, Zoological Society of India, 34 Chittaranjan Avenue, Calcutta 12.

The Royal Society and the Nuffield Foundation Commonwealth Bursaries

AWARDS under the Royal Society and Nuffield Foundation Commonwealth Bursaries Scheme have been announced as follows: Prof. G. M. Badger, professor of organic chemistry, University of Adelaide, to assist him to visit Cambridge during January–May 1959, in order to study recent advances in organic chemistry, with special reference to natural products; Prof. J. H. Blaney, professor of mathematics, University College of Ghana, to enable him, during September 1958–January 1959, to have discussions and work with mathematicians at Sydney and Singapore with interests in number theory close to his own; Dr. W. Cochran, lecturer in physics, University of Cambridge, to enable him to travel to Chalk River in order to acquire experience of neutron diffraction techniques, for about a year from August 1958; Mr. A. B. Cribb, lecturer in botany, University of Queensland, to enable him to examine type and other specimens of marine algae, particularly early collections of Australian algae, at the British Museum (Natural History), Kew and other British herbaria, for a year from January 1959; Dr. R. H. Estey, of the Department of Plant Pathology, Macdonald College, McGill University, to assist him to learn new and different techniques in plant pathology and mycology, at Nottingham for two months from July 1958; Prof. T. Gillman, professor of physiology, University of Natal, to enable him to study certain special problems of regeneration of skin, principally at University College, London, during January–July 1959; Dr. P. Gray, lecturer in physical chemistry, University of Leeds, to enable him to study free radical reactions by mass spectrometric and electron-spin resonance techniques at Vancouver, for nine months from September 1958; Prof. H. Kleerekoper, professor of zoology, McMaster University, to enable him to collect and study limnological data from Lake Moneague, Jamaica, in July and August 1958, in order to add to the knowledge of the relationships between biological productivity and the physical and chemical nature of the bottom sediments of a tropical lake; Prof. R. J. Rossiter, professor of biochemistry, University of Western Ontario, to enable him to continue research on the biogenesis of phospholipids, at Canberra for a year from December 1958; Dr. G. Salt, lecturer in zoology, University of Cambridge, to assist him to visit West Pakistan for about six months from October 1958 in order to extend his work on the reactions of insect hosts to ichneumoid parasites and to attempt to apply it to the control of insect pests of crops by means of parasites; Dr. D. A. Scogings, senior lecturer in land surveying, University of Natal, to enable him to travel to University College, London, in July 1958 in order to carry out research in photogrammetry for about six months; Dr. T. B. Teoh, lecturer in pathology, University of Hong Kong, to assist him to study bile thrombi as a means of throwing light on the problems of non-obstructive biliary cirrhosis, at University College Hospital Medical School, London, for a year from September 1958; Dr. C. E. Wright, senior scientific officer, Plant Breeding Station, Loughgall, Northern Ireland, to enable him to study work in New Zealand on blind seed disease of ryegrass for seven months from September 1958.

"Administration and Defence in a Technical Age"

Reference is made in the editorial article under this title in *Nature* of June 28 to the contribution by Mr. R. Blake to "Soldiers and Government". Mr. Blake has pointed out that, although he is in full agreement with what is said by Mr. M. Howard in his introductory essay, he himself is responsible only for the essay on Great Britain.

Announcements

The Rennie Memorial Medal for 1957 of the Royal Australian Chemical Institute has been awarded to Dr. J. H. Bradbury. The H. G. Smith Memorial Medal has been awarded to Dr. K. L. Sutherland for his research work on flotation and allied fields.

The Duke of Northumberland, who was appointed chairman of the Agricultural Research Council some time ago, has now taken office in succession to Lord Rothschild, who retired on June 30 after ten years service as chairman.

The British Association, after sixty-seven years in Burlington House, is moving into a suite of offices in the house belonging to the Royal Society of Arts. From July 14 the address of the Association will be: 18 Adam Street, Adelphi, London, W.C.2. Telephone Trafalgar 5733/4.

The Trustees of the Ciba Foundation, wishing to encourage well-conceived research relevant to basic problems of ageing, invite candidates to submit papers descriptive of work in the field for the fifth and final awards, which are to be made in 1959. Further information can be obtained from Dr. G. E. W. Wolstenholme, Director and Secretary to the Executive Council, Ciba Foundation, 41 Portland Place, London, W.1.

An International Congress on the Modern Educational Treatment of Deafness will be held in the University of Manchester during July 15–23. The Congress has been organized at the request of the Ministry of Education. Further information can be obtained from Jean N. Howarth, Department of Education of the Deaf, The University, Manchester 13.

An informal discussion of the Faraday Society on Free Radical Stabilization will be held in the Department of Chemistry of the University of Sheffield on September 4 and 5. Further particulars can be obtained from Dr. B. Stevens or Dr. H. T. J. Chilton, Department of Chemistry, University of Sheffield.

At the invitation of the Hellenic Society for the Protection of Nature, the Sixth General Assembly of the International Union for Conservation of Nature and Natural Resources will be held jointly with its Seventh Technical Meeting, in Athens, during September 11–19. Further information can be obtained from the International Union for Conservation of Nature and Natural Resources, 31 rue Vautier, Brussels.

The first International Congress in the Aeronautical Sciences, organized by the International Council of the Aeronautical Sciences, will be held in Madrid during September 8–13, when Dr. Theodore von Kármán will preside. The programme is being arranged by committees under the chairmanship of Prof. Maurice Rey, director of the Office National d'Etudes et de Recherches Aeronautiques, Paris; and by Col. A. Perez-Marin, technical secretary-general, Istituto Nacional de Technica Aeronautica, Madrid. British scientists or technologists wishing to attend should apply to Dr. A. M. Ballantyne, 4 Hamilton Place, London, W.1. The address of the Secretariat of the International Council of the Aeronautical Sciences is: Institute of Aeronautical Sciences, 2 East 64th Street, New York 21, N.Y.

THE FLOW OF BLOOD IN RELATION TO THE VESSEL WALL

A MEETING was held on June 13 to discuss the flow of blood in relation to the vessel wall, at the Charing Cross Hospital Medical School, London, by invitation of the Clinical Research Sub-Committee of the Hospital.

The chairman, Dr. N. C. Lake, welcomed nearly a hundred guests to what was probably the first meeting ever called specifically to discuss 'hæmorheology'. We sometimes regret the invention of still more names for the smaller branches of science; nevertheless, Dr. Lake pointed out, hæmorheology covers a very significant and important field of study, which is really wider than that of hæmodynamics. He briefly outlined a number of problems in surgery and medicine in which the nature of the flow of blood must play a crucial part. (An account of the medical aspects of the discussion will be published elsewhere.)

Dr. G. W. Scott Blair (University of Reading), a rheologist, then read a paper entitled "A Survey of Work on Flow of Blood through Tubes". He pointed out that blood is not far removed from a true (Newtonian) fluid in its behaviour when flowing through narrow tubes, but its deviations from such behaviour are very important. First, any non-spherical particles will tend to align themselves statistically in the direction of flow. Secondly, larger and heavier particles will tend towards the centre of the stream, leaving a layer devoid of particles near the walls. Thirdly, clumping of red cells not only causes them to displace white cells but also tends to increase the 'viscosity' (defined as the ratio shear stress/rate of shear) in the region of low stress, namely, in the centre, in such a way as to flatten the figure of extrusion. This resembles superficially the effects of turbulence; but, although turbulence of various kinds may occur, especially in large vessels, the two phenomena should not be confused. The importance of changes in the relative concentrations of the components of blood resulting from these radial distributions may be expected to be considerable.

Historically, these deviations from the Poiseuille–Hagen law have been studied by two independent and often disconnected groups of workers. The empirical facts concerning the flow of blood have been developed since the time of Poiseuille by a number of authors; in recent decades mainly in Sweden. The theoretical study of these anomalies has accompanied measurements in quite other systems, including paints, clays and plastics. Only recently have the two lines of work converged, to great mutual advantage.

Dr. A. L. Copley, who directs the Research Unit recently set up at Charing Cross Hospital for the study of hæmorheology, then read a paper giving the results of his experiments, *in vitro*, or more correctly, '*non-in-vivo*', since many of the glass surfaces of his viscometers were coated with fibrin, silicone, etc. He used two methods of experiment. In the first, the blood, serum or plasma is contained in a horizontal tube, the central portion of which is narrow, while the two ends are of the same diameter and much wider. The flow is timed over a selected distance in the wider tube, where viscous resistance and surface tension are negligible. The material can be sheared backwards and forwards at different pressures through capillaries of different radii and, if necessary, lengths, while deviations from the fourth-power radius and inverse length laws are measured. The viscometer was checked with a true fluid, sucrose solution, and was found to be satisfactory.

The second apparatus is a tilting-tube viscometer, in which an 'index' of liquid is timed as it slides down the tube at different angles of tilt. Extra pressure can also be applied if desired. Here a correction must be made for surface tension, unless the angles of contact at the two ends of the index are identical, which is seldom the case.

When indexes of blood or its components flow fairly fast down these tilted tubes, a layer is left behind, adhering to the wall, and the thickness of this layer can be calculated. At large angles the sines of which differ but little, samples flowing at the same speeds give adherent layers of a thickness which depends on the angle of tilt.

Preliminary but very encouraging experiments were also described showing significant differences in adherence and in flow-rates when the walls of the tube had been coated with fibrin, silicone, etc. Dr. Copley briefly outlined his theory of the part played by fibrin and fibrinogen in the endothelium.

Dr. P. H. Staple described his work with Dr. Copley on biomicroscopic observations *in vivo* of the plasmatic zone in the capillary beds of frogs and of Syrian and Chinese hamsters. His drawings showed clearly the presence of Poiseuille's 'marginal zone' and, by adding graphite particles and dyestuffs to the flowing material, the authors were able to confirm, for the first time, a number of observations on the effects of rates of flow of blood on the immobile portion of the marginal zone, postulated by Poiseuille more than a century ago.

Many points were raised in discussion on these three papers. Prof. K. Weissenberg stressed the complexity of rheological phenomena and spoke of the causes of different types of turbulence and of flow instability. Other speakers raised points concerning the nature of viscous anomalies in blood, and it was pointed out that it is not possible to infer the presence of adherent layers in full capillaries from the presence of layers which are left behind when an index flows down an inclined tube. Dr. Copley believes, however, from other evidence, that there must be some relationship between adherence of indexes and that in full capillaries.

Two visitors from abroad then addressed the meeting. Prof. M. H. Knisely, of the Department of Anatomy, Medical College of South Carolina, showed a beautiful colour film illustrating the movement of red and white cells in the living animal. Under pathological conditions, the red cells form a sludge which tends to collect along the bottom of the larger vessels. Deep sludges are, of course, well known in post-mortem conditions, but Prof. Knisely's film showed them in anæsthetized animals which were still alive. Observations had also been made on vessels in the eyes of very ill and even dying patients. It was claimed that, in perfect health, red cells show no agglutination whatever and, indeed, repel one another.

Dr. F. K. Beller, of the University of Tübingen, also read a short communication on micro-coagulation processes on the vessel wall, in which he said that the verification by Drs. Copley and Staple of Poiseuille's claims concerning the plasmatic zone threw much light on hitherto inexplicable results.

The chairman, in closing the meeting, said that it was clear from the vigour of the discussion that the subject had provoked much interest. It was hoped that similar meetings would be arranged in other places where work on the flow of blood is being undertaken.

G. W. Scott Blair

SEDIMENTATION AND OROGENY

THE Fifth International Congress of Sedimentology was held in Geneva and Lausanne during June 2–7, under the joint chairmanship of Prof. Augustin Lombard and Dr. Arnold Bersier, and was attended by more than 160 members from eighteen different countries. About forty-five papers were presented, covering diverse aspects of recent and ancient sedimentation. The central theme of the Congress, however, was the nature and origin of flysch and molasse, and excursions in the Pre-Alps and in the Mittelland were arranged for the study of these deposits in the field.

To many of the Swiss geologists flysch and molasse were clearly terms peculiar to the Alpine orogeny and, despite Marcel Bertrand's wider application of them as early as 1894, never designed for export. Even with this limited usage the gradual application to them of both a lithological and a stratigraphical significance has led to the establishment of such anomalies as "Flysch à faciès molasse" and "Molasse à faciès flysch". Since molasse has also been defined as a rock type (by Lucien Cayeux) the term may be used with a petrographical, facies or stratigraphical significance.

Nevertheless, it was evident that most members of the Congress employed the terms as descriptive of facies and sought criteria whereby the syn-orogenic and post-orogenic sediments of mountain chains other than the Alps might be recognized. Typical of the studies having this end in view were those from Russian contributors describing Upper Carboniferous 'flysch' and Permian 'molasse' from the Urals–Volga oil-bearing region. The most familiar development of the flysch is the regular alternation of shales with poorly sorted micaceous sandstones, often graded and convolute and carrying, at their bases, a variety of cast structures and trace-fossils. It was, of course, pointed out that any or all of these features may be lacking in considerable thicknesses of flysch successions and that none of them is necessarily confined exclusively to syn-orogenic sediments. Nevertheless, there was general agreement that, when present together, they provide an assemblage characteristic of such deposits. The relative proportions of sand and shale in the flysch were regarded as an indication of the distance of the zone of deposition from the rising mountain front.

Opinion differed widely regarding the depth of water in which the flysch was deposited. American communications dealing with modern marine sediments, especially those off the southern Californian coast, made it clear that basins at a depth of 1,000 metres or more are filling with sands interbedded with normal deep-water muds. These were compared with Pliocene basins in California, completely filled with a similar sequence of sediments, where the shales are believed to have served as source beds of petroleum for which the sandstones now provide the reservoirs. The association of Eocene flysch (on the Spanish side of the Pyrenees) with neritic sediments, as described in another communication, however, suggests that depth of water is not necessarily a critical factor. It was noteworthy that the majority of geologists working on modern marine sedimentation accepted turbidity currents as widespread agents of clastic deposition. While the general opinion clearly regarded them as playing an important part in the formation of flysch, doubts were expressed of the need to regard all flysch-type sediments as having originated in the same way.

The change from syn-orogenic to post-orogenic sedimentation must inevitably be gradual and a vertical transition from flysch-type to molasse-type sediments or an alternation of the two facies is likely to be the rule rather than the exception. Confusion arises only where the terms are used in a stratigraphic sense. Molasse, with its massive sequences of poorly sorted sandstones, often strongly current-bedded and associated locally with thick conglomerates (*Nagelfluh*), and with its evidence of intraformational erosion and of cyclical sedimentation, has a characteristic lithology, though in petrographical character its individual units may not differ markedly from those of flysch. Confusion is unfortunately caused by the use of 'macigno' as a petrographical term (following Omalius d'Halloy, Brongniart and Cayeux) for the micaceous sandstone with a mixture of calcareous and argillaceous cementing material which is a common lithology in the molasse. In the Macigno formation of the Apennines the same rock type with beautiful grading, convolutions and sole-markings occurs interbedded with shales in a succession regarded by the Italians as typical flysch.

In the molasse, even more than in the flysch, there is a pronounced zonal distribution of lithologies, with conglomerates bordering the new mountain chains and fine sandstones and shales, often with evaporites, on the external margin of the fore-trough. A number of communications dealing with the petrographical and lithological features of the molasse emphasized the variation to be anticipated between one paralic basin and another and the difficulties to be faced in attempting to reconstruct the history of the final stages of an orogeny from purely sedimentary evidence.

The papers presented at the Congress are to be published as a special number of *Ecologae geologicae Helvetiae*. At the meeting of the International Association of Sedimentology, held during the final session of the Congress, Dr. F. P. Shepard, of the Scripps Institution of Oceanography, was elected president in succession to Prof. C. W. Correns.

J. H. Taylor

ASSOCIATION FOR RADIATION RESEARCH

SOME 170 persons attended the seventh meeting of the Radiation Research Visiting Club held at the Medical Research Council Experimental Radiopathology Research Unit, Hammersmith Hospital, on May 9 and 10. About 100 were present at the open business meeting at which the need for a rather more formal organization was debated under the chairmanship of Prof. F. S. Dainton. This meeting brought to an end the first phase in the existence of the Club, which hitherto has had no rules, no committee, and no subscription, its only existence between meetings having been a list of 'member centres' with some names of individual radiation research workers. The whole responsibility for each meeting has rested on the hosts who have come forward with invitations, and they have been at liberty to arrange the meetings entirely as they wished. The informality of the meetings and the absence of organization appealed to most of those who attended, and many felt very reluctant to start a new scientific society or association. It was generally agreed, however, that the need had become pressing, for two main reasons: the numbers of research workers who had become interested had grown so large that membership on an individual basis was clearly necessary; also, some form of organization was needed to establish and maintain liaison nationally and internationally with bodies having similar or related interests. It was resolved, therefore, that an Association be formed.

The Visiting Club originally sprang from a desire on the part of scientists of different disciplines to meet together in each others' laboratories to discuss topics of mutual interest in the field of radiobiology in which they were working. The meetings of the Club have shown that the subject of radiobiology is broad enough to bring together a group of convenient size. It is probable that other branches of radiation research such as radiation chemistry could do the same. The issue most keenly debated at the recent meeting was whether the organization which the meeting proposed to bring into being should be an Association of people who were meeting primarily on the common ground of radiobiology—with the corollary that similar group organizations would be established for other branches of radiation research—or whether an attempt should be made to establish an organization which would meet the needs of all radiation research workers. As the name of the Association implies, the latter alternative was chosen, and one of the objects of the new Association was defined as being: "To bring together research workers of different disciplines, having a common interest in radiobiology, radiation chemistry and radiation physics".

It was the express wish of those present at this and previous meetings of the Visiting Club that the scientific business of the Association should be "conducted mainly according to the precedent set by meetings of the Radiation Research Visiting Club which have been held before the formation of the Association", and this proviso was incorporated in the constitutional rules which were agreed upon as a minimum operational requirement. From now on, however, the privilege of attending these meetings will be reserved for members of the Association.

Other constitutional rules were decided on which defined the conditions for eligibility to membership—"any person actively interested in the fields covered by the objects of the Association shall be eligible for election to membership"—and the composition of the committee, which everyone agreed should include radiation research workers from varied fields of interest. The first committee, elected for a two-year period, is as follows: chairman, Dr. L. H. Gray; honorary secretary, Miss T. Alper, Experimental Radiopathology Research Unit, Hammersmith Hospital, Ducane Road, London, W.12; honorary treasurer, Dr. C. L. Smith; ordinary members, Prof. A. Charlesby, Prof. F. S. Dainton, Dr. Alma Howard, Dr. J. F. Loutit, Prof. J. S. Mitchell, Dr. Edith Paterson.

The annual subscription was fixed at 10*s*., and it was agreed that anyone who has attended any of the seven meetings of the Radiation Research Visiting Club should qualify for membership without election. Any others wishing to join the Association should be proposed and seconded by members who know them personally. Forms for the purpose may be obtained from the honorary secretary and should be returned by the proposer with accompanying letter of recommendation. It is hoped that the first election of new members will take place at a business meeting which will be held in conjunction with the first scientific meeting of the Association. This will probably take place early in 1959, in Newcastle on Tyne, at the invitation of Prof. J. Weiss. Particulars will be circulated in due course to all who have become members of the Association by the appropriate time.

Most radiation research workers have affiliations with learned societies in their own specialty. The Visiting Club has never duplicated the activities of any learned society, but has set out to bridge the gaps between different disciplines. If, in its larger context, the Association can foster an exchange of knowledge and experience in the same friendly and intimate way as the Club has done, we feel that its future is assured.

FRITZ LONDON AWARD

THE fifth International Conference on Low Temperature Physics and Chemistry, held at the University of Wisconsin during August 26–31, 1957, was the occasion of the presentation of the first Fritz London Award. The Award is to be made biennially and carries an honorarium of 1,000 dollars, together with an expense allowance of 500 dollars. The recipient was Dr. N. Kurti, of the Clarendon Laboratory, Oxford, and the texts of the introductory remarks made by Dean F. G. Brickwedde (Pennsylvania State University) and by Prof. J. G. Daunt (Ohio State University), who made the presentation, together with the address entitled "Nuclear Orientation and Nuclear Cooling" delivered by Dr. Kurti, are printed in the March 1958 issue of *Physics Today*. In a preceding article in the same issue, Dr. J. Wilks (Clarendon Laboratory, Oxford) gives a report of the general proceedings of the conference.

In his remarks, Dean Brickwedde paid tribute to Fritz London for his wide range of contributions to physics and for his philosophical approach to research. He thanked Arthur Little, Inc., for their generosity in sponsoring both the first and second Fritz London Awards, and mentioned that much of the great expansion in cryogenic research since the end of the Second World War was due to this firm because of its manufacture and improvement of the Collins helium cryostat. Prof. Daunt briefly outlined Dr. Kurti's accomplishments in the field of low-temperature physics, referring especially to his investigations at temperatures less than 1° K.

Dr. Kurti, in his address, explained first the essential connexion between nuclear orientation and cryogenics, and then summarized the four basic equilibrium methods of nuclear orientation—magnetic hyperfine structure alignment, magnetic hyperfine structure polarization, external field polarization, and electric hyperfine structure alignment. All four methods have been realized experimentally, the first both at Oxford and Leyden initially in 1951, the second in Oxford about a year later, and the third and fourth in Oak Ridge in 1955 and 1956, respectively. The nuclear orientation experiments had as their chief aim the study of the anisotropy of the gamma-ray emission in a variety of radioactive decay schemes, and by combination of the results with data obtained by conventional nuclear physics methods and by paramagnetic resonance, the decay schemes of some twenty nuclei have been established. Dr. Kurti particularly directed attention to the recent celebrated experiment on parity conservation carried out by E. Ambler, R. W. Haywood, D. D. Hoppes, R. P. Hudson and C. S. Wu at the National Bureau of Standards, pointing out that this had required considerable skill in cryogenics and had brought nuclear orientation methods into the limelight.

Dr. Kurti then turned to consider how nuclear orientation could help in solid state physics, and gave two examples of how, if the decay scheme and hence the gamma-ray anisotropy to be expected is known, the oriented radioactive nuclei may be used as indicators for certain properties. Finally, he dealt in some detail with nuclear cooling, that is, the production of very low temperatures by isentropic demagnetization of polarized nuclei. The idea was first mentioned explicitly in 1933 by C. J. Gorter, and by N. Kurti and E. F. Simon, and the possibilities of attaining the very large values of H_i/T_i (initial magnetic field and temperature) required were discussed by Simon in 1939. The final successful experiments were performed in 1956 (see *Nature*, **178**, 450; 1956), and Dr. Kurti described in his address the four steps in a magnetic cooling experiment; the construction of a suitable cryostat for nuclear cooling using magnetically cooled manganous ammonium sulphate, and the results of a series of nuclear demagnetizations all starting from $T_i = 0{\cdot}012^\circ$ K. and from fields, H_i, ranging between 3·5 and 28 kilo-œrsteds. The lowest temperature measured was about 20 microdegrees. It should be possible, Dr. Kurti asserted, to increase the value of H_i/T_i four or five times, thus reducing the nuclear entropy by about 40 per cent from its ideal value. The demagnetization would then lead to a temperature below the nuclear Curie point and the nuclear ordering could be ascertained. Another worth-while problem would be the cooling of other substances into the microdegree temperature range, and it would seem that on theoretical grounds alone there should be no fundamental difficulty. Thus eventually, Dr. Kurti forecast, microdegrees would assume a similar place in cryogenics to that occupied by millidegrees to-day.

S. Weintroub

RESEARCH FOR INDUSTRY

UNDER the title "Research for Industry"*, the Department of Scientific and Industrial Research has published a useful summary of the work done by the industrial research associations which the Department assists with grants, covering the fifteen months ended December 30, 1957. "Research for Industry", which corresponds with the summary that formerly occupied about one-third of the Department's annual report, will in future be published separately for each calendar year and generally appears to follow the pattern of its predecessor. Although it gives an interesting picture of the many-sided contribution which the research associations are making to the national life, it does not—and a summary of this character could scarcely be expected to—facilitate assessment of the place of the movement in industry, or its strength or weakness in relation to other institutions, whether from the point of view of research, of education, or of the dissemination of information.

Although most of the research associations issue annual reports, a few points of general interest may be noted to illustrate the wide scope of the movement. The British Baking Industries Research Association, for example, is examining a new milling technique which permits the alteration by mechanical means, to a greater extent than previously, of the protein/starch ratio in the several flour fractions produced, and promises to permit the production from relatively poor quality flour of fractions suited for specialized purposes. The British Boot, Shoe and Allied Trades Research Association has made good progress with new methods of training operatives whereby girls may be fully trained in six weeks. The British Cast Iron Research Association's work on de-phosphorizing foundry iron, which should permit greater use to be made of British ores high in phosphorus for making iron castings, has reached a promising stage.

The British Ceramic Research Association, which in the past few years has made a particular study of the control of dust in those processes in which the health of the operative is at hazard, and has succeeded in controlling dust in the towing and fettling of earthenware on an industrial scale, is now focusing attention on the corresponding problems in the sanitary earthenware and tile industries. The British Coal Utilization Research Association has developed a new design of ash pan for railway locomotives for use with inferior coal, while the British Coke Research Association is seeking the best methods for disposing of liquid effluent from coke-oven plants and establishing the standards of purification required for effluents which are disposed of to rivers and sewers.

* Department of Scientific and Industrial Research. Research for Industry: a Summary of work done by the Industrial Research Associations in the Government Scheme, 1956–57. Pp. iv+159. (London: H.M. Stationery Office, 1958.) 7*s*. 6*d*. net; 1.35 dollars.

The automatic hardening machine designed by the Cutlery Research Council to reduce the labour required for the operation to 25 per cent of that needed for the conventional method represents the Council's first major attempt at mechanization. Machines developed for the classification of fine powders, depending on the opposing action of centrifugal force and inward air-drag, have been used by the Research Association of British Flour-Millers to make cuts in flour at production-rates of commercial interest, giving, for example, a higher protein half of better bread-making quality and the other half of better cake-making quality than the original flour. Large-scale canning trials by the Fruit and Vegetable Canning and Quick Freezing Research Association indicate that the antibiotic, nisin, has potential application in controlling the spoilage of canned vegetables by heat-resistant thermophilic bacteria.

Besides devising apparatus to determine at any time the stage to which glass melting has proceeded, the British Glass Industry Research Association has given much attention to the role of instrumentation and automatic control of furnace conditions, while electronic methods devised by the Hosiery and Allied Trades Research Association have enabled lengths of stockings to be controlled automatically within very close limits. A simple investigation of flow in small open channels by the British Hydromechanics Research Association has permitted the designer to reduce the number of down pipes in a length of building by one-half and has also pointed to a slight modification of the outlet design which can double the capacity of the system.

The British Iron and Steel Research Association has applied the statistical technique of regression analysis to establish correlations between the many factors that affect the performance of blast furnaces, and the British Jute Trade Research Association has developed an anti-corrosive wrapping material for bright steel parts. The Motor Industry Research Association is investigating a promising method of reducing noise in vehicles by damping the vibration of body panels, and the work of the Research Association of British Paint, Colour and Varnish Manufacturers has included the structural features of paint films, the molecular make-up of the medium in film form and the character and disposition of the pigment particles.

An entirely new process for the production of paper pulp from graminaceous raw materials, devised by the British Paper and Board Industry Research Association, gives greatly increased yields, and the Printing, Packaging and Allied Trades Research Association continued its study of the hazards of transport and how packages stand up to them. The British Rayon Research Association has put on the market the warp tension balance, which enables the loom overlooker to control the incidence of repping, and an electronic tensiometer, for the correct setting of yarn spinning and processing machinery; and a study of productivity in the process of mastication and mixing by the Research Association of British Rubber Manufacturers has greatly increased production.

In its methodical tests on models of ocean-going merchant vessels, the British Shipbuilding Research Association is giving much attention to the problem of hull roughness. The Coil Spring Federation Research Organization is studying the effect of variations in manufacture and materials on the fatigue life of heavy suspension springs, and the British Steel Castings Research Association has started a long-range investigation on the factors determining the efficient utilization of oxygen in electric furnace steel-making. The Coal Tar Research Association has given particular attention to factors influencing the purification of naphthalene by fractionation and by crystallization.

AIRFLOW OVER MOUNTAINS

IT has been recognized for many years that regular patterns of motion of a wave-like type may occur in the air flowing over and to the lee of mountain ranges. This seems to have been realized first from the clouds which—given suitable conditions of temperature and humidity—form in the ascending currents of the waves and which are more or less stationary although obviously situated in a strong wind. The rising and falling components of wind in these waves are of importance to aviation as they may cause the aircraft to rise, or more important, descend in a dangerous manner. They have frequently been used by glider pilots as a means of ascent. The wave patterns can occur at considerable distances above and beyond the mountain range responsible and must be distinguished from the irregular turbulent flow set up in the immediate vicinity of the peaks and steep parts of the mountains. The waves are most readily produced by long ranges transverse to the wind.

Much theoretical study has been devoted to the mechanics of the waves in the past twenty years, the most successful theory being due to Dr. R. S. Scorer of the Imperial College of Science and Technology, London. Dr. Scorer's theory has been well verified by the experiences of aircraft pilots and other observations, so that it now appears justifiable for aviation weather forecasters to use it in attempting to predict the occurrence of waves.

Dr. Scorer showed that waves will form only if the vertical gradient of temperature and wind speed in the air to windward of the range are suitable. His theory in fact states that waves will form if the quantity termed l^2, which is given by:

$$\frac{g}{T}\,\frac{\left(\Gamma + \frac{dT}{dz}\right)}{U^2} - \frac{1}{U}\,\frac{d^2U}{dz^2}$$

(where T is the absolute temperature, Γ is the numerical value of the dry adiabatic lapse-rate, U is the wind speed, and Z the height), decreases with height. In fact, and fortunately, the difficult second term is of small account compared with the first term, which can be calculated with sufficient accuracy from observations.

From the formula, considering only the first term, it follows that waves are to be expected if the temperature gradient decreases (lapse-rate increasing, in the usual meteorological terminology) with height, or wind speed increases, or there is a suitable combination of both effects.

In Meteorological Report No. 18*, Mr. G. A. Corby of the Meteorological Office describes how Dr. Scorer's theory can be exploited by forecasters when advising pilots on the nature of the airflow over mountains. He gives a number of reports of waves encountered by aircraft, and shows how the occurrence of the waves in question was to be expected from the atmospheric structure. A suitable diagram for computing l^2 is given with instructions for its use in forecasting.

The report also contains diagrams of the flow of air in lee waves computed from the general theory and an account of such effects as the increase in liability to ice formation, given suitable air temperature and humidity, in the waves because the ascent of the air has the effect of lowering the height of the freezing-level.

G. A. Bull

MOUNT STROMLO OBSERVATORY

REPORT FOR 1957

The annual report of Mount Stromlo Observatory for 1957* deals first with the transfer of the Observatory to the Australian National University on January 3, 1957, when the Commonwealth Observatory of the Department of the Interior officially ceased to exist. All the members of the scientific staff of the Observatory were transferred to the Department of Astronomy of the Research School of Physical Sciences of the Australian National University, the official name of the Observatory then becoming 'Mount Stromlo Observatory'. Arrangements were made not only to safeguard the financial status of the staff but also to protect an area of about 3½ square miles in which the Observatory buildings are situated "from invasion by industry, commerce or any development relating to the growth of the nearby capital city of Canberra".

Following the departure of Dr. R. v. d. R. Woolley in December 1955, Dr. A. R. Hogg assumed the post of acting director of Mount Stromlo Observatory, a position which he retained until Dr. Woolley's successor, Dr. B. J. Bok, took office in March 1957, and on his arrival became head of the newly formed Department of Astronomy at the Australian National University. Tribute is paid to the valuable work accomplished during Dr. Hogg's tenure of office, and on Dr. Bok's arrival he was appointed assistant director.

Tests of the 74-in. mirror by Dr. Hogg, with the assistance of Mr. K. Gottlieb, proved the existence of astigmatism in excess of the maximum permissible amount, and while steps are being taken to remedy this, the telescope during the interim is used for photoelectric, spectrographic and photographic work. Under Dr. Hogg's direction the mirror was successfully aluminized. The 50-in. Melbourne reflector has been overhauled in the Design Department and the workshop. Motorization of the fast motion in right ascension has been completed and provisions have been made for Selsyn repeater systems in both declination and right ascension. Other alterations have been made and an important work plan is well under way to replace the present $f/2$ spherical primary with an $f/4{\cdot}5$ paraboloid and a conventional Cassegrain mirror for the entire system to operate at $f/18$. The 30-in. Reynolds reflector, which continues to be in regular use, is overdue for a complete mechanical and electrical overhaul. Short notes appear on the other instruments, including the 20-in. Catts reflector, the 8-in. $f/1$ Schmidt, and the photographic zenith tube, and considerable space has been devoted to Dr. T. Dunham's plans for a coudé spectrograph on the 74-in. reflector. The spectrograph will be enclosed in a housing with double walls 24 ft. long and 16 ft. wide, and air at constant temperature will circulate between the two layers of the wall, thereby avoiding thermal effects on the instrument.

Among other matters dealt with are observation of artificial Earth satellites. It is emphasized that Mount Stromlo Observatory is not officially involved in the observation of artificial satellites and the names of other institutions and also individuals are referred to in connexion with this work. Nevertheless, *Sputnik I* was kept under observation, and later Dr. A. Przybylski carried out observations of other satellites and did a considerable amount of work on their orbits. He also issued duplicated copies of predicted times of observation which proved to be very reliable.

Eight vacation scholars selected from undergraduate students in physics and mathematics at the Universities of Melbourne, Adelaide, Queensland and Sydney were appointed for the summer months, and each scholar has been assigned as a special assistant to a staff member. These scholars hold weekly colloquia, attend weekly informal discussion meetings, and participate in the night observing, acting as night assistants on the 74-in. reflector during staff vacations. They live in University House, conduct the visitors around during the day-time and participate fully in many other Observatory activities. It is hoped that during 1958 the first appointments will be made to regular scholarships leading to the Ph.D. degree.

Public visits to the Observatory both by day and night have been remarkably popular; to accommodate the great demand for visits by night the Director has instituted a series of monthly visitors' nights, with an average attendance of 150 people, and on these nights most telescopes are open for inspection. Estimates of the number of visitors show that there have been about 3,500 day-time visitors, 500 Wednesday visitors and 1,000 visitors during the seven special evenings. A booklet has been issued which gives information about the Observatory and its work. A list of the names of the twenty-two members of the Observatory staff and a catalogue of papers published during 1957 appear at the end of the report.

A SIMPLE TECHNIQUE FOR INOCULATING PATHOGENIC BACTERIA ON SUSCEPTIBLE PLANT LEAVES

By M. A. NOUR and J. J. NOUR

Faculty of Agriculture, Shambat, University of Khartoum, Republic of the Sudan

DURING an investigation of virus diseases of 'lubia' (*Dolichos lablab* L.) an extract of the virus-infected leaves was mixed with a small amount of 'Carborundum' (300 mesh) and rubbed on healthy leaves in the normal way. It was observed that when the leaves used as a source of inoculum contained a few lesions of bacterial disease, numerous lesions of the bacterial infection developed on the rubbed leaves. The causal agent was the *Dolichos* strain of *Xanthomonas phaseoli* (Smith) Dowson[1].

Several inoculation tests were made by rubbing either the crude extract (in 10 ml. water) of 10 gm. fresh weight of *Dolichos* leaves infected with *X. phaseoli* or by rubbing a suspension of the pure culture of this pathogen on to healthy leaves of 'lubia' with ($+ C$) or without ($- C$) 'Carborundum' in both cases. The 'undiluted' suspension was obtained by adding 7 ml. distilled water to a 'slope' of 10 ml. yeast-extract agar upon which the pure culture was grown. By scraping and shaking, the yellow turbid suspension was obtained. In another experiment, different dilutions of the crude extract or of a 2–3 day old pure culture suspension were separately mixed with an equal volume of a 1 per cent solution of anhydrous sodium sulphite[2], or with water (as control), and were rubbed on to healthy leaves. This test was made to confirm the earlier observation that a larger number of bacterial spots formed when sodium sulphite, rather than when water, was used with the leaf extract.

In a third series of tests, other related species were rubbed with the crude extract from *Dolichos* leaves heavily infected with *X. phaseoli*, namely, *Phaseolus vulgaris* L., *Canavalia ensiformis* (L.) DC., *Vigna unguiculata* (L.) Walp., *Cajanus cajan* L., *Lupinus termis* Forsk. and *Crotallaria saltiana* Andr.

'Carborundum' in all comparable tests gave a large number of bacterial lesions, many more than in the controls (Table 1). When 'Carborundum' was used, the typical water-soaked lesions appeared after 5–7 days, as compared with 7–10 days when it was not.

The results obtained did not confirm the original observations that sodium sulphite induces the formation of significantly more local lesions than water. Very similar results were obtained with young Domain Sakel cotton plants (*Gossypium barbadense* L.) and a pure culture suspension of *Xanthomonas malvacearum* (Smith) Dowson (Table 2). When 'Carborundum' was used, with both 'lubia' and cotton, a significantly larger number of lesions developed in areas that were mechanically injured than on the apparently undamaged parts.

Table 1. EFFECT OF 'CARBORUNDUM' USED WITH INOCULUM IN RUBBING HALF LEAFLETS OF *Dolichos lablab*

Dilution	Lesions per half leaflet			
	With sodium sulphite		With water	
	$+ C$	$- C$	$+ C$	$- C$
1 : 1	584	33	463	31
1 : 2	388	50	250	25
1 : 4	520	44	300	27
1 : 8	300	26	240	16

Table 2. EFFECT OF 'CARBORUNDUM' WHEN USED WITH INOCULUM IN RUBBING HALF LEAVES OF EGYPTIAN COTTON

Dilution	Lesions per half leaf			
	With sodium sulphite		With water	
	Dec. 5	Dec. 9	Dec. 5	Dec. 9
1 : 1	50	340	58	360
1 : 10	131	525	66	355
1 : 10*	3	26	0	23
1 : 100	16	142	51	190

* $- C$.

In the third series, only *D. lablab* showed symptoms of infection. This *Dolichos* strain is specialized enough, therefore, not to cause an infection (or even sub-infection) even when 'Carborundum' is used.

To compare this technique with the standard methods of inoculating bacteria on leaves[3], several tests were done. In one, the first leaves of young *Dolichos* plants were sprayed with a 1 : 1 or 1 : 10 suspension of the bacteria from pure culture, leaving one lot of each in the open and covering the others with bell jars. On another set of first leaves the same dilutions were rubbed, with or without 'Carborundum'. The water-soaked lesions appeared on the leaves treated with 'Carborundum' 4–6 days before those sprayed and covered (Table 3). Again, similar results were obtained when the two methods were applied on young cotton plants, using *X. malvacearum*.

Table 3. EFFECT* OF SPRAYING AS COMPARED WITH MECHANICAL RUBBING ($+ C$) OF INOCULUM ON WHOLE LEAVES OF *D. lablab*

Dilution	Sprayed		Rubbed
	In bell jar	Open	$+ C$
1 : 1	38	16	> 1,000
1 : 10	14	2	> 1,000

* Average number of lesions per whole first leaf (10 replications) caused by *X. phaseoli*.

This new technique for bacterial inoculation has several advantages. It is highly economical with the inoculum and is simple and easy to apply. Furthermore, the use of high-humidity chambers after inoculation is unnecessary to ensure heavy infections. Another advantage is that the symptoms appear earlier than when the standard spraying method is used. However, the greatest advantage is that the pathogen can be placed exactly where it is required to form lesions of infection.

We gratefully acknowledge the assistance of Dr. K. A. Sabet, head of the Agricultural Botany Department in this Faculty, for identifying the pathogens, for supplying the pure cultures and for his valuable suggestions.

BIOCHEMICAL MUTANTS IN BACTERIA WITH IMPAIRED RESPIRATION

By Prof. G. F. GAUSE

Institute of Antibiotics, Academy of Medical Sciences, Moscow

MUTANT strains of staphylococci, with impaired respiratory activities, have been used in the screening of antibiotics to pick out those selectively inhibiting cells with the deficient respiration[1]. These investigations, which formed part of a search for anti-cancer substances, stimulated studies on the production of similar mutations in different species of bacteria.

In *Staphylococcus aureus*, Strain 209, mutations with the respiratory deficiency were induced by ultra-violet radiation[2]. The mutants grew slowly on nutrient agar, producing small colonies which differed from the parent strain in being orange-rose in colour. Their respiration was studied, using Warburg manometry at 37° C. in a medium containing sodium chloride 0·138 *M*, sodium bicarbonate 0·003 *M*, and glucose 0·0555 *M*. Average Q_{O_2} values (μl./hr./mgm. dry weight) were: parent strain 104·0; mutant No. 2 48·0; mutant No. 3 38·1. The addition of 0·012 *M* sodium cyanide inhibited respiration of the parent strain by 86·1 per cent, whereas it inhibited that of mutant No. 2 by 45 per cent and mutant No. 3 by only 14·5 per cent. In other words, the respiratory activity of these biochemical mutants of staphylococci was greatly reduced and was also less sensitive to cyanide, relative to the parent strain[3]. These characteristics of the mutant strains have proved stable, through numerous subcultures, at least for a period of one year.

It is remarkable that the parent culture of staphylococci and the two mutants obtained from it do not differ from each other in their sensitivity to penicillin and to streptomycin, whereas albomycin only inhibits growth of the parent culture and is no longer active against either mutant culture[2]. This is probably related to the fact that albomycin inhibits the growth of bacteria only in the presence of oxygen[4]; perhaps mutant cultures of staphylococci with the impaired respiration no longer possess a specific receptive substance affected by albomycin.

Spectroscopic studies with a Zeiss microspectroscope have shown that, whereas in the parent strain three α bands of cytochromes are distinctly visible (strong b_1 band at 560 mμ, and two smaller bands, *a* at 605 mμ and a_2 at 625 mμ), in both mutant strains band b_1 is no longer visible[3].

Further studies have shown that in *Bacterium coli* and *Bacterium paracoli* biochemical mutations with impaired respiration could also be obtained[3,5]. They are induced by ultra-violet radiation and particularly by urethane, which, as is well known, has a strong carcinogenic action upon the cells of higher animals and inhibits cytochrome electron transport. On nutrient agar, containing 2 per cent urethane, a few rare mutants can be found with the hereditary impairment of respiration among slowly growing colonies of parent culture. These mutants grew slowly on nutrient media without urethane, and have not changed their characteristics in subcultures for a long period of time.

The impairment of respiration in these mutant strains is clearly seen from the following data[3,5]:

	Q_{O_2}
B. coli, parent culture 5383	138·5
B. coli, ultra-violet mutant 8	62·7
B. coli, parent culture 5375	178·0
B. coli, ultra-violet mutant 9	63·7
B. paracoli, parent culture	173·0
B. paracoli, urethane mutant 52–1	42·0
B. paracoli, urethane mutant 52–2	40·5
B. paracoli, ultra-violet mutant 12	36·0
B. paracoli, ultra-violet mutant 15	43·8
B. paracoli, ultra-violet mutant 17	54·2

The respiration of these mutants is also less sensitive to inhibitory action of 0·012 *M* sodium cyanide as compared to their parent strains[3]. Microspectroscopic examination of thick suspensions of living cells of these mutants produced some very instructive results, shown in Fig. 1.

The parent strains of both *B. coli* and *B. paracoli* possessed three distinct α bands, namely, a_2 at 625 mμ, *a* at 605 mμ, and the strong b_1 band at 560 mμ. In all mutant strains the intensity of the *a* band was strongly increased, and in some of them it was shifted from 605 to 600 mμ. Most important of all, however, was the fact that the b_1 band at 560 mμ had disappeared in all mutant cultures, and was

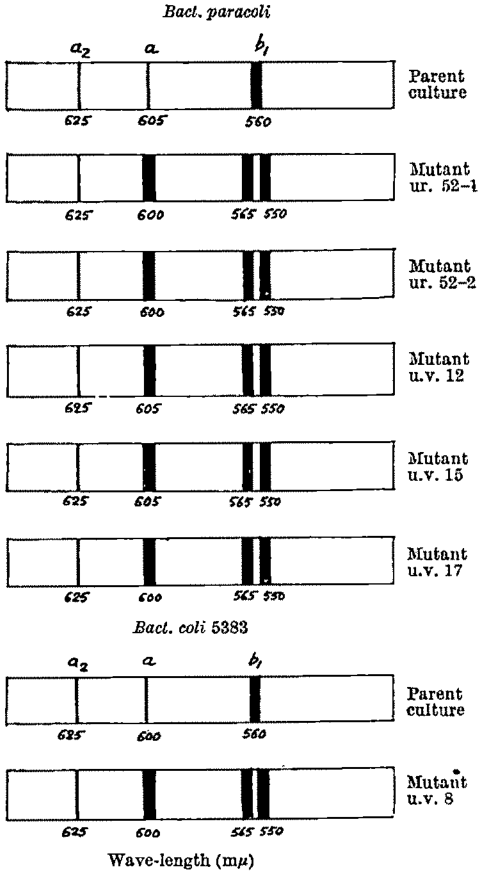

Fig. 1. Cytochrome spectra in parent cultures of *B. coli* and *B. paracoli*, and in six mutations with the impaired respiration obtained from them

actually replaced by two new strong bands, at 550 and 565 mμ. In view of suggestions[6] that the cytochrome b_1 band in *B. coli* results from the fused bands of cytochromes *b* and *c*, the appearance in the mutant with impaired respiration of two new strong bands in the *b* and *c* positions, instead of the characteristic b_1 band of the parent culture, is very remarkable. These characteristic alterations in cytochromes of the mutant cultures of *B. coli* and *B. paracoli* evidently accompany the functional inefficiency of their respiratory system, as it can be judged by the low value of Q_{O_2} and by the decrease of cyanide sensitivity of the oxygen consumption.

Mutant cultures with the impaired respiration in *Bacillus mycoides* (smooth form) were also obtained[5]; they were induced by the combined action of ultra-violet radiation and of urethane. Values of Q_{O_2} at 28° C. were: parent strain 52·8; mutant No. 2 37·0; mutant No. 4 43·3. The respiration of mutant strains was also less sensitive to the inhibition by cyanide as compared to the parent strain—for example, 0·012 *M* sodium cyanide inhibited respiration of the parent strain by 68·5 per cent, mutant No. 2 by 19 per cent, and mutant No. 4 by 30·5 per cent.

Spectroscopic studies showed that the parent culture of *B. mycoides*, in common with many other aerobic spore-forming soil bacteria, possessed the following α bands in its cytochrome spectrum: *a* band at 603 mμ, and two wide bands, almost merging, *b* at 563 mμ, and *c* at 552 mμ. In both mutants of *B. mycoides* with impaired respiration, the *b* band of cytochrome at 563 mμ was no longer visible; the *a* and *c* bands remained essentially the same as in the parent culture.

The mutants in staphylococci, *B. coli* and *B. paracoli* and in *B. mycoides* with impaired respiration, all share the following common features: decreased Q_{O_2} values, and a diminished sensitivity of their respiration to cyanide. However, their respiratory deficiencies are accompanied by different alterations of the cytochrome systems in different bacteria; in staphylococci the cytochrome b_1, and in *B. mycoides* the cytochrome *b*, are no longer visible. In *B. coli* and *B. paracoli* the band of cytochrome b_1 disappears, and two new bands appear in its stead. It is remarkable in this connexion that in the intact ascites tumour cells in mice with impaired respiration[7], spectroscopic study[8] has also revealed a deficiency in cytochrome *b*.

A plea has recently been made for a more rational approach in chemotherapeutic research[9]. Bacterial mutants with impaired respiration seem to represent, in this connexion, very convenient tools for detection of antibiotics and of other substances selectively inhibiting cells with deficient oxidative powers; such substances present interesting therapeutic potentialities, particularly in cancer research.

PIGMENTS AND PHOTOSYNTHESIS IN A CAROTENOID-DEFICIENT MUTANT OF *CHLAMYDOMONAS*

By DR. RUTH SAGER
Department of Zoology, Columbia University, New York

AND

DR. MARKO ZALOKAR
Department of Microbiology, Yale University, New Haven, Conn.

THERE are many reports in the literature of mutations affecting the formation of chlorophyll and carotenoid pigments[1]. In general, these mutations decrease the chlorophyll content either independently of, or concomitant with, a lowered carotenoid content. Similarly, environmentally induced alterations of pigment content have involved decreases in chlorophyll relative to carotenoid. Many non-green plant tissues contain large amounts of carotenoids. However, no instance has been reported, to our knowledge, in the algae or in higher plants, of the formation or occurrence of chlorophyll in the absence of carotenoids. (In the photosynthetic bacterium *Rhodopseudomonas spheroides*, blue-green mutants have been described which contain bacteriochlorophyll and no coloured carotenoids[2].)

This article describes a pale-green mutant strain of the alga *Chlamydomonas reinhardi*, which contains chlorophyll but only traces of carotenoids. This strain, No. 95, and several others which resemble it, were recovered after ultra-violet irradiation of normal green cells. These strains are very stable, no reversion to normal green having appeared at any time since the initial isolation, either in stock cultures or in the many litres grown for pigment analysis. Because of the poor growth-rate of these strains, it is probable that reversions to or towards wild type would have a selective advantage, and therefore would have been readily detected had they occurred.

Preliminary examination with the electron microscope[3] of the pale-green mutant has revealed the presence of a chloroplast in which the total amount of lamellar surface is greatly reduced from that of the normal green strain[4]; only a few scattered lamellar membranes are present. In studies using the double-beam spectrophotometer[5] it was determined that the mutant responds to illumination by uptake of carbon dioxide, release of oxygen, and oxidation of respiratory enzymes including cytochromes of the *b* and *f*-types. Thus, the pale-green mutant carries out photosynthesis. Its photosynthetic efficiency, on a chlorophyll basis, is greater than that of the wild type. None the less, the mutant dies when grown in the light, whether cultured photosynthetically on a minimal medium or heterotrophically on a medium which supports its growth in the dark.

In view of the many questions as yet unresolved concerning the role of carotenoids in photosynthesis, in the structural organization of the chloroplast lamellæ, and in protection from the lethal effects of

Table 1. CAROTENOID CONTENT OF NORMAL GREEN AND PALE-GREEN STRAINS OF *Chlamydomonas*

* These values can be converted approximately to mgm./100 gm. dry weight by the factor 25.
† Values in parentheses refer to an inflexion in the spectrum rather than a peak.

light, it was of particular interest to determine the carotenoid content of this pale-green strain. There are no reports in the literature concerning the carotenoids of *Chlamydomonas*, except for those of Moewus on protocrocin and its derivatives[6]. The carotenoids of *Haematococcus*, a closely related genus, have been studied by Tischler[7] and by Goodwin[8]; *b*-carotene and xanthophyll are predominant in the green stages, while the red cysts contain mainly astaxanthin. In addition, there are minor pigments, of which aphanin, aphanizophyll and violaxanthin have been identified.

This article reports the chlorophyll and carotenoid content of the pale-green strain in comparison with that of the normal green strain from which it arose. The major carotenoids were separated by chromatography and identified, and the minor pigments were characterized by their spectra and chromatographic behaviour.

Cells were grown for pigment extraction in liquid medium, containing acetate and inorganic salts[9], and harvested by centrifugation at the end of the logarithmic phase of growth, at densities of 1–5 × 10^6 cells/ml. for the pale-green, and about 1 × 10^7 cells/ml. for the normal green strain. The starting material for carotenoid extraction contained, in the normal green strain grown in light, 152 mgm. protein, in the dark-grown normal green, 35 mgm. protein, and in the pale-green mutant, 240 mgm. protein. Protein was estimated, after acetone extraction, by the biuret reaction and compared with a standard of bovine albumen[10]. Chlorophyll was extracted from washed fresh cells with 85 per cent acetone; optical density was determined in acetone with a Beckman spectrophotometer, and total chlorophyll computed by the method of McKinney[11].

Carotenoids were extracted from fresh frozen cells with methanol, saponified with potassium hydroxide and transferred to hexane. Epiphasic and hypophasic pigments were separated by shaking the hexane solution with 90 per cent methanol. Epiphasic pigments (carotenes) were chromatographed on magnesium oxide and developed with 10 per cent acetone-hexane. Hypophasic pigments (xanthophylls) were chromatographed on calcium hydroxide and developed with 10 per cent acetone-hexane containing 1 per cent ethanol. All pigments were rechromatographed and their spectra taken with a recording spectrophotometer.

b-Carotene was obtained in crystalline form and identified by its spectrum and by a mixed chromatogram with a known sample. Xanthophyll was identified by its spectrum, partition behaviour, and by a mixed chromatogram with a sample obtained from spinach; *a*-carotene was identified by its spectrum and chromatographic behaviour. Other pigments could not be identified positively, and the spectra of some are different from those of any known carotenoid.

The chlorophyll and carotenoid content of the pale-green mutant was compared with that of the normal green strain grown both in the light and in the dark; the same acetate medium was used throughout. The carotenoid pigments recovered are listed in Table 1, in decreasing order of adsorption on the chromatographic columns. Concentrations were calculated from known extinction coefficients, and in the instance of unknown pigments, the extinction coefficients *E*(1 per cent, 1 cm.) were assumed to be 2,500 at the absorption maximum.

The pale-green mutant was found to contain less than 0·5 per cent of the total carotenoid of the light-grown normal green strain, and less than 0·2 per cent of the carotenoid of the dark-grown normal green. This trace of carotenoid consists of *a*- and *b*-carotene; no other constituents were detected.

No phytoene or phytofluene was found in either pale-green or normal green cells. They would have

Table 2. CHLOROPHYLL CONTENT AND CHLOROPHYLL–CAROTENOID RATIOS OF NORMAL GREEN AND PALE-GREEN STRAINS OF *Chlamydomonas*

	1 Normal green (light-grown)	2 Normal green (dark-grown)	3 Pale-green (dark-grown)	Ratio 1/3	Ratio 2/3
Chlorophyll conc., moles/gm. protein	$1·55 \times 10^{-4}$	$1·02 \times 10^{-4}$	$8·61 \times 10^{-6}$	18	8·5
Total carotenoid, moles/gm. protein	$1·05 \times 10^{-5}$	$2·58 \times 10^{-5}$	$4·84 \times 10^{-8}$	217	533
Ratio chlorophyll/carotenoid	14·8	3·96	178		
β-Carotene, moles/gm. protein	$6·58 \times 10^{-6}$	$1·48 \times 10^{-5}$	$3·58 \times 10^{-8}$	184	413
Ratio chlorophyll / β-carotene	23·6	6·9	241		

been detected if present in concentrations as low as 10 μgm. per gm. protein. Astacene, which would have been derived from astaxanthin with the extraction procedure used, was also absent.

Light-grown normal green cells were found to contain a number of carotenoid pigments, with *b*-carotene as the major constituent, and others present in small amounts. In dark-grown normal green cells, there was more than twice as much carotenoid present as in light-grown cells, with the bulk of it, too, consisting of *b*-carotene. However, few of the other pigments were found; one component, xanthophyll, was predominant. Thus, it appears that either light or some step in the photosynthetic pathway enhances the formation of a number of minor pigments, possibly at the expense of xanthophyll.

Data on chlorophyll concentration of the two strains are given in Table 2, together with comparisons of chlorophyll/carotenoid ratios. Despite the low chlorophyll content of the pale-green mutant, it is noteworthy that its chlorophyll/carotenoid ratio is still much higher than that of the normal green strain, because of its exceedingly low carotenoid content.

It was estimated[11] that about 60 per cent of the chlorophyll of normal green cells is present as chlorophyll *a*; the rest is *b*. In the pale-green mutant, about 90 per cent of the total is chlorophyll *a*.

The pale-green mutant which was the subject of this study has about 1/15 the chlorophyll and less than 1/200 the carotenoid content of the normal green strain from which it was derived by mutation. This decreased pigment content and high chlorophyll/carotenoid ratio does not interfere with the photosynthetic capacity of the strain. On the contrary, its 'assimilation number' (moles carbon dioxide taken up/mole chlorophyll/sec.) is higher than that of the normal green strain[5], a finding analogous to that reported by Willstater and Stoll for golden varieties of the number of plants[12].

Our findings support the hypothesis that carotenoids are not essential for green plant photosynthesis, except possibly in catalytic amounts. The occurrence of photosynthesis in the apparent absence of carotenoids has also been reported for a blue-green mutant of *Rhodopseudomonas spheroides*[2], which contains bacteriochlorophyll and the colourless carotenoid, phytoene. In discussing this mutant, Calvin[13] suggested that an essential part in photosynthesis, normally played by carotenoids, may be provided in the mutant by "the less conjugated phytoene". Since no phytoene is found in the pale-green *Chlamydomonas* mutant, this hypothesis is at present inapplicable in our material. With respect to the absence of phytoene and phytofluene, the *Chlamydomonas* mutant also differs markedly from the mutants of *Chlorella*[17] and of *Neurospora*[16], and phenocopies obtained with diphenylamine[16] which have been described.

Lynch and French[14] have provided preliminary evidence of the need for *b*-carotene or a related compound in the Hill reaction as carried out by lyophilized broken chloroplast preparations. In their experiments, Hill activity is completely lost after extraction of just a few per cent of the carotenoid. One may question, therefore, how specifically the changes in Hill activity depend upon this small change in carotenoid content, or whether the extraction and recoating process affects the system indirectly.

The pale-green mutant dies when grown in the light either photosynthetically or heterotrophically. This lethal effect of light resembles that described for the blue-green *Rhodopseudomonas* mutant[2]; and the hypothesis that carotenoids protect cells from "photodynamic destruction by chlorophyll"[2] may also apply to the pale-green mutant. On the other hand, the correlated lack of carotenoids and photosensitivity could represent independent results of some more basic deficiency.

The low carotenoid content of the pale-green strain is of interest also in connexion with structural features of the chloroplast as seen with the electron microscope. The lamellar membranes typical of the chloroplasts of all normal green cells including *Chlamydomonas*[4] are found in the pale-green mutant, although their number is much reduced. This finding contrasts with that reported for the yellow mutant of *Chlamydomonas*[15], in which lamellæ do not form in the absence of chlorophyll. When the yellow mutant is brought from dark growing conditions into light, chlorophyll synthesis is initiated and lamellar formation proceeds in parallel[3]. Thus chlorophyll is required for the formation of lamellar membranes, and probably is incorporated as a necessary component into the membranes.

In the pale-green mutant, the reduction of lamellar surface is approximately 20-fold in comparison with the normal green cell, a value which correlates better with the 10- to 20-fold reduction in chlorophyll concentration than with the 200- to 500-fold reduction in carotenoids observed. It is likely, therefore, that carotenoids are not required for the formation of lamellæ, and furthermore, may not represent an essential component of photosynthetically active membranes. In normal green cells, on the other hand, carotenoids probably are incorporated into the membranes, judging from the participation in action spectra of photosynthesis[12] of wavelengths of visible light absorbed principally by carotenoids.

On the question of stoichiometry of constituents of the membranes, it may be noted that the chlorophyll/carotenoid ratio in the pale-green mutant is almost fifty times that in the dark-grown normal green. If the few carotenoid molecules present in the pale-green strain are, in fact, incorporated into the membranes, then their arrangement with respect to the other components must be very different from that in the normal green cells.

This work was supported in part by grants from the National Science Foundation and the U.S. Public Health Service.

A STEGOLOPHODON FROM SOUTH AFRICA

By Dr. RONALD SINGER
Anatomy Department, University of Cape Town

AND

DICK A. HOOIJER
Rijksmuseum van Natuurlijke Historie, Leiden

During an expedition to the Elandsfontein fossil site[1], 10 miles from Hopefield (about 60 miles north-west of Cape Town), we visited the Langebaan Phosphate Quarries (of the African Metals Corporation), which are 10 miles north-north-west of that site. Fossils are known to have been excavated during blasting operations, and on this occasion we were shown some specimens recently recovered by a prospector, Mr. I. S. Brown. This preliminary report deals with only one of these specimens. It was found in Baard's Quarry on the farm Langberg in a phosphate deposit about 15 feet below the surface. Below the sandy surface layer is a layer of phoscrete, below which is a thicker layer of clay and phosphatic nodules. Under this is a 12-in. layer of solid phosphate in which the specimen was found. Details of the geological interpretation of the stratified layers are still awaited.

Other fragments were found with the specimen being recorded, but unfortunately the prospector discarded these and a search for them is still to be undertaken. We are indebted to Mr. A. Coreejes, superintendent of the quarry, for kindly giving the specimen to the South African Museum, Cape Town. Its registered number is S.A.M. 11714.

It is a portion of a right upper molar comprising the last two ridges. The hindmost ridge is just in wear and consists of five subequal cones; the two cones on the buccal side are placed somewhat more forward than the other (Fig. 1). Behind and between the two buccal cones there is a fairly large cone, which is in line with the cones in the lingual part of the hind ridge. In turn between it and the central cone of the hind ridge there is a much smaller cone, which together with it represents the talon (Figs. 1 and 2). The posterior margin of the crown is smoothly rounded from side to side, with the base projecting backward slightly more lingually than buccally. The transverse width of the posterior ridge is 62 mm. at base; the height of the almost unworn central cones is 30 mm.

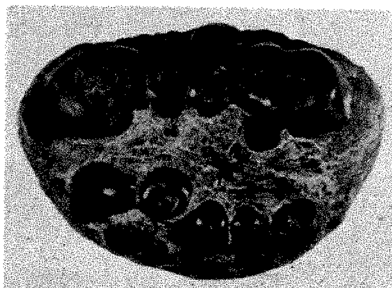
The valley in front of the hindmost ridge is closed in at the bottom. It is filled with cement that extends to the apices of the cones of the hind ridge, and there are two tiny enamel cusps at its lingual entrance (Fig. 3). The cement layer has been lost on the buccal and lingual edges of both ridges as well as on the posterior surface of the crown. There is a natural cleft in the cement limited to the lingual half of the valley between the two ridges (Fig. 1).

The second ridge from behind measures 75 mm. across the base. However, the gingival margin of the crown is incomplete on both sides of the ridge, and the full width of the ridge may have been about 80 mm. The cones of the second ridge are six in number. There are two central cones flanked by two massive cones each of which is imperfectly subdivided into a small central and a larger lateral cone. The two central cones are separated from each other as well as from the cones on each side by clefts that continue to the base of the crown (Fig. 4). The combined width of the two central cones is 18 mm. measured along the occlusal surface, the same as that of each pair of cones on either side. The apices of the dentine cores of all the six cones have just been reached by wear; the ridge is slightly more worn down on the buccal than on the lingual side. The maximal height of the worn ridge is 35 mm. The slope of the buccal edge of the ridge is less steep than that of the lingual edge; this effect is produced by a bulge towards the base of the buccal part of the crown (Fig. 1).

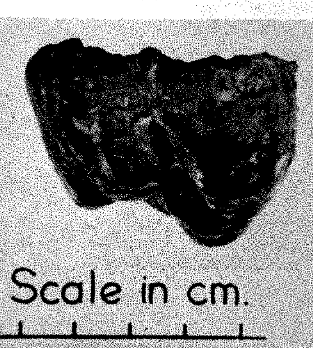
As a whole the second ridge shows a gentle forward transverse convexity. This appearance is reflected by the posterior wedging of the two small cones flanking the central pair of cones. The lingual of the two central cones has a forward bulge, while the posterior surface of the extreme lingual cone exhibits a truncated bulge where it meets the adjoining cone (Fig. 1). The buccal central cone has a small nodular projection on its posterior surface 5 mm. from the occlusal edge.

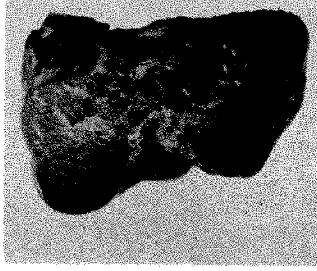
The roots have broken off, and there is no evidence of the central pits of the cones, which are completely covered by dentine on the upper (root) aspect of the specimen.

(1)

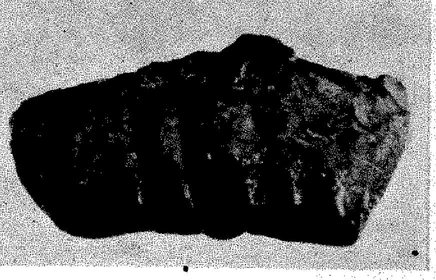


(2)





(3)



(4)

It is not possible to state definitely what the serial position of the present specimen is, but because of the stage of wear and the absence of a posterior pressure mark it is considered probable that it is a last molar, M^3 dext.

The Langebaan specimen presents a combination of mastodont and stegodont features. The low, thick-enamelled and squat lateral cones and the presence of an anterior bulge on the median cone simulating an intermediate conule indicate the mastodont affinities. The stegodont features are: the absence of a median cleft in the posterior ridges, the closure of the enamel in the base of the valley, and the arrangement of the cones in transverse rows, although the cones are not quite united into ridges to the degree seen in a true *Stegodon*. There can be no doubt as to the generic assignment of the specimen: it belongs to the genus *Stegolophodon*, which is characterized by this peculiar blending of mastodont and stegodont features[2].

The stegolophodonts represent the most primitive stegodonts. Although originally Osborn[3] included them in the Stegodontinæ, he later erected a new subfamily, the Stegolophodontinæ, for the inclusion of these forms[3]. Simpson[4] again placed them in the Stegodontinæ. In the Indian Siwaliks the single genus *Stegolophodon* ranges from the Chinji, through the Dhok Pathan and the Tatrot into the Pinjor, that is, Lower Pliocene to Lower Pleistocene. It also occurs in the Lower Pleistocene of Borneo[3]. The genus has recently been recorded by Petrocchi from Sahabi in Cyrenaica, North Africa[5,6]. He attributed the fauna in 1941 to the Miocene (?), while in 1943 it is included in the Pliocene; Hopwood and Hollyfield[7] refer the material from the Cyrenaican site to the Pliocene (?). Lower Pleistocene molars from East Africa described as *Archidiskodon planifrons nyanzae* by MacInnes[8] have been regarded by Arambourg[9] as probably belonging to *Stegolophodon*, but the specimens in question do resemble primitive archidiskodont molars so closely as to make it highly improbable for them to represent a stegolophodont.

The faunal remains obtained from nearby phosphate quarries in the Langebaan area similar to that which yielded the *Stegolophodon* represent *Rhinoceros*, *Equus*, *Sivatherium*, antelopes cf. *Oreotragus*, cf. *Damaliscus* and cf. *Redunca*, and a large buffalo, cf. *Homoioceras*. All these are essentially Pleistocene types but they are derived from limestone deposits while the *Stegolophodon* was found in the phosphate layer at a deeper level. It is probable that the limestone deposits are Upper Pleistocene whereas the phosphate layer is Middle or Lower Pleistocene. Therefore, it is most likely that the South African *Stegolophodon* is Middle Pleistocene in age.

The Langebaan stegolophodont is widely different from the bunolophodont mastodont described from the higher terrace (60–80 feet) of the Vaal River at Waldeck's Plant near Kimberley by Beck[10] and by Fraas[11]. The latter is still the only mastodont ever to have been described from South Africa.

The fossil molar fragment described in the present article provides the first evidence for the occurrence of the genus *Stegolophodon* in Southern Africa.

Because of the fragmentary nature and uncertain serial position of the Langebaan *Stegolophodon* molar, we prefer to abstain from a specific determination. Until more complete specimens have been obtained the stegolophodont of South Africa may be recorded as *Stegolophodon* sp.

One of us (D. A. H.) is visiting South Africa on a grant from the Netherlands Organization for Pure Research (Z.W.O.). The other (R. S.) is indebted to the South African Council for Scientific and Industrial Research and the Wenner-Gren Foundation for Anthropological Research, New York, for generous grants for research at the Hopefield site.

GLUCOSE CATABOLISM IN THE AMERICAN COCKROACH

By GABRIEL M. SILVA*, W. P. DOYLE and DR. C. H. WANG

Departments of Agricultural Chemistry and Chemistry and Science Research Institute,
Oregon State College, Corvallis, Oregon

ENZYMATIC studies on the carbohydrate metabolism in insects, mostly flies and cockroaches, have revealed the operation of the Embden–Meyerhof–Parnas glycolysis[1], and a direct oxidative pathway, possibly of the pentose cycle type[2], as the major catabolic routes for the utilization of glucose in the insects. Recent tracer studies reported by Wintering-ham *et al.*[3], using acetate labelled with carbon-14, as well as other enzymatic work[4], provided evidence supporting the occurrence of the tricarboxylic acid cycle for the metabolism of acetate in flies. However, information is not yet available concerning the relative importance of these catabolic pathways of glucose in intact insects.

In this laboratory, time-course studies on the utilization by intact cockroaches (*Periplaneta americana*) of glucose specifically labelled with carbon-14 have been carried out. Respiratory carbon dioxide was collected during prescribed time intervals from the cockroaches metabolizing the labelled glucose administered by means of injection techniques[5]. Radioactive assay of the carbon dioxide samples so obtained provided confirmatory evidence for the operation of glycolysis and a direct oxidative pathway for the primary breakdown of glucose in this species.

TETRAZOLIUM SALTS

Tetrazolium salt (2:3:5-triphenyl-tetrazolium chloride) used for seed testing and as a biological stain, is issued by B.D.H. as a material of high purity and sensitivity. A B.D.H. Technical Bulletin, obtainable on request, summarizes the many references to it in the literature.

In some applications blue tetrazolium and iodo-tetrazolium, which are mentioned in the Bulletin, have advantages over tetrazolium salt.

The use of iodo-tetrazolium to measure the degree of spoilage of white fish is suggested in a recent communication from Shewan and Liston (*J.Sci. Food Agric.*, 1957, **8**, 222). Tetrazolium violet is also now available.

Ups and downs . . .

on a surface that should be smooth are a constant source of trouble to the engineer. How is he to remove things that he may not be able to see ? The answer is to make them visible with an interferometer, which will show them plainly, even though they amount to no more than a fraction of the wavelength of light. We, of course, make all sorts of interferometers and interferometric apparatus—some for measuring lengths, some for increasing the resolving power of spectroscopic instruments, some for testing prisms and lenses, and some for examining surfaces and measuring their irregularities.

¶ The photograph shows a steel slip-gauge with a scratch across its surface, seen through a Hilger surface micro-interferometer. The interference fringes form a 'contour map' of the surface, and if the surface were truly flat, the fringes would be straight, parallel, and sharply defined.

NEVILLE BROWN & CO. LTD., 77 Newman Street, London, W.1

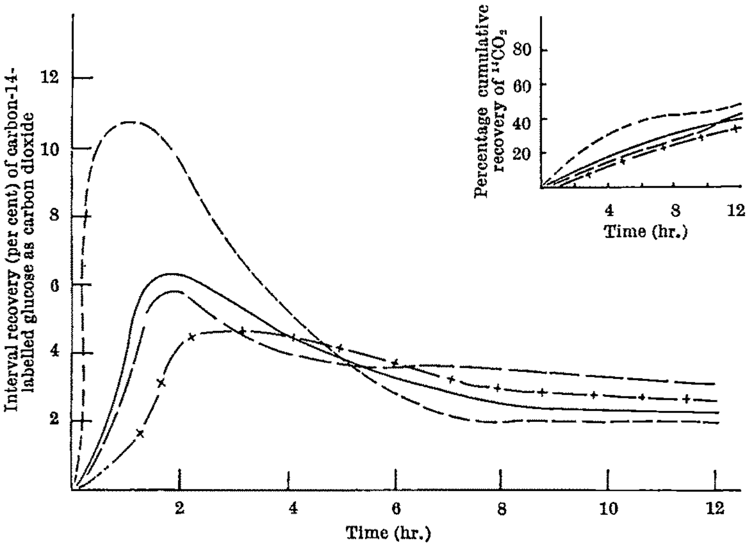

Fig. 1. Interval recovery of carbon-14 in expired carbon dioxide from *P. americana* metabolizing glucose labelled with carbon-14 : ——, glucose-1-^{14}C ; — —, glucose-2-^{14}C ; - - -, glucose-3(4)-^{14}C ; — + —, glucose-6-^{14}C

It was estimated that the latter pathway is responsible for the metabolism of only 4–9 per cent of the glucose administered in the intact cockroaches.

Essentially, the time-course experiments were carried out in a manner similar to that reported by Wang *et al.*[6] for the study of glucose metabolism in yeast. Usually 32 cockroaches, fasted for 12 hr. and divided into four groups having equal total body-weight, were used in each series of experiments. To each cockroach in the group was administered a solution of the labelled glucose, having a concentration of 250 mgm. per ml. and a specific activity of 1·8 μc./m.mole. The dose used was generally 23 μl. per gm. of cockroach. Glucoses-1,2,3(4) and 6 labelled with carbon-14 were used in each experiment (obtained through the co-operation of Dr. Isbell of the National Bureau of Standards, except in the case of glucose-3(4)-^{14}C, which was prepared in this laboratory according to the method of Wood *et al.*[7]). The cockroaches used in the present experiments were six-month adults, furnished by Dr. A. Mallis, of the Gulf Research Co. of Pittsburgh, Pennsylvania, through Prof. P. O. Ritcher, of Oregon State College. Males were used exclusively on account of their strikingly high respiratory-rate (ref. 1*c*). After the injection of the substrates, the cockroaches were kept in metabolic bottles maintained at 28° C., respiratory carbon dioxide being collected and assayed for carbon-14 by conventional techniques.

The interval radiochemical recoveries of substrate activity in the respiratory carbon dioxide from cockroaches metabolizing the specifically labelled glucose obtained in a typical experiment are given in Fig. 1. Satisfactory reproducibility was observed upon completion of scores of identical experiments. It is evident that the Embden–Meyerhof–Parnas glycolysis, in conjunction with pyruvate decarboxylation, is the major pathway for primary breakdown of glucose as indicated by the rapid recovery of the bulk of C-3(4) of glucose in carbon dioxide. The acetate produced in the foregoing processes is probably metabolized further by the conventional tricarboxylic cyclic process[3]. This is also indicated by the finding that, soon after the phase of rapid conversion of C-3(4) of glucose to carbon dioxide, C-2 of glucose began to appear in carbon dioxide at a rate constantly higher than that of C-6 until 3 hr. after the injection. The finding is understandable if one supposes that C-2 and C-6 of glucose correspond to the carboxyl and methyl carbon atoms of acetate respectively. Operation of the conventional tricarboxylic acid cyclic processes would then call for a preferential combustion of the carboxyl carbon of acetate to carbon dioxide in the early stages. That an alternate pathway is operating in the cockroaches for the primary breakdown of glucose is shown by the observed preferential recovery of C-1 of glucose in carbon dioxide as compared with that of C-6. In view of the reported activity of glucose-6-phosphate dehydrogenase and 6-phosphogluconate dehydrogenase in insects[2], it is reasonable to believe that the alternate pathway observed here in our cockroach experiments is of the phosphogluconate decarboxylation type, although the extent of the operation of the pentose cycle for the metabolism of pentoses cannot be determined in the present work.

The cumulative percentage radiochemical recoveries of substrate activity in carbon dioxide from cockroaches metabolizing glucose-1,2,3(4) and 6-^{14}C, designated respectively as G_1, G_2, $G_{3(4)}$ and G_6, are given in the insert of Fig. 1. The estimation of the individual catabolic pathways of glucose in the cockroaches were made using the method of Wang *et al.*[6]. Bearing in mind the assumptions made in the original paper[6], the extent of operation of individual catabolic pathways for the glucose administered can be expressed in the following equations :

Percentage (min.) of glucose metabolized by the phosphogluconate decarboxylation, designated G_p, is given by :

$$G_p = G'_1 - G'_6 \qquad (1)$$

where G'_1 and G'_6 represent percentage cumulative radiochemical recoveries of substrate activity in carbon dioxide from cockroaches metabolizing glucose-1-^{14}C and glucose-6-^{14}C respectively, at the time the glucose administered has been completely catabolized in the system. In the present work, the latter time was chosen as 6 hr., since at that moment the rate of recovery of C-3(4) of glucose in carbon dioxide has decreased to a much lower but steady level which reflects the exhaustion of the readily available labelled glucose in the insect.

Percentage (max.) of glucose metabolized by the glycolytic pathway, designated G_e, is given by :

$$G_e = 100 - G_p \qquad (2)$$

since it was assumed that there are only two pathways functioning in this organism.

It is understood, however, that in the foregoing equation it is assumed that the labelled glucose administered to the cockroaches was completely catabolized degradatively to its breakdown products. On the other hand, a portion of the glucose administered may have been incorporated into polysaccharides or other fractions containing glucose in its entirety. This would then necessitate an experimental determination of the amount of the labelled glucose actually engaged in catabolic functions during the experimental period before the estimation of individual pathways can be made. It appears that the fraction of carbon-14 labelled glucose actually metabolized degradatively in the insect can be estimated approximately by the following equation :

$$G_t = (G_1 - G_6) + G_{3(4)} \qquad (3)$$

where G_t is the percentage of carbon-14 labelled glucose engaged in insect catabolism up to time t; G_1, G_6, $G_{3(4)}$ are percentage radiochemical recoveries of substrate activity in carbon dioxide up to time t from cockroaches metabolizing glucose-1-^{14}C, glucose-6-^{14}C, and glucose-3(4)-^{14}C respectively.

Equation 3 is derived from the view that for each mole of glucose catabolized glycolytically 1 mole of carbon dioxide from either C-3 or C-4 of glucose will be produced, and for each mole of glucose catabolized via the direct oxidative pathway 1 mole of carbon dioxide from C-1 of glucose in excess of that from C-6 of glucose will be produced. Using the value of G_t so obtained, it is then possible to estimate the extent of operation of individual catabolic pathways of glucose as follows :

Percentage (max.) of glucose metabolized by the phosphogluconate decarboxylation, G'_p, is given by :

$$G'_p = \frac{(G_1 - G_6) \times 100}{G_t} \qquad (4)$$

and the percentage (min.) of glucose metabolized by the glycolytic pathway, G'_e, is given by :

$$G'_e = 100 - G'_p \qquad (5)$$

Using this method, it was found that in intact male adult cockroaches, glucose is catabolized by way of the direct oxidative pathway to an extent of only 4–9 per cent, and the bulk of glucose is catabolized by adult male cockroaches six months old via the Embden–Meyerhof–Parnas glycolytic pathway. The latter, in conjunction with tricarboxylic acid cyclic processes, is probably responsible for the respiratory activity and biosynthetic functions in this insect. It is quite possible that the observed small amount of activity of the direct oxidative pathway is primarily for the purpose of pentose production.

EXPERIMENTAL ALLERGIC ENCEPHALOMYELITIS

Production of Experimental Allergic Encephalomyelitis in Guinea Pigs with Fractions isolated from Bovine Spinal Cord and Killed Tubercle Bacilli

For many years, allergic encephalomyelitis has been produced experimentally in animals by injection of a mixture containing whole brain or cord and whole killed tubercle bacilli. Many attempts have been made to fractionate the active material in nerve tissue, but tests on these fractions have always been carried out with whole killed tubercle bacilli in the adjuvant mixture. Recently, Colover and Consden[1] have reported that certain residues from tubercle bacilli possessed the same ability as the whole organism to sensitize the animal to the encephalitogenic effects of brain. Their tests were run on tubercle bacillus fractions combined with whole brain.

With Dr. Colover's co-operation, 'purified' fractions have been exchanged and combinations of cord and tubercle bacillus fractions have been tested in each laboratory. The results of our tests on these fractions are reported here.

The cord fraction which Colover tested in his laboratory was a collagen-like protein of molecular weight around 40,000, which has been found to be homogeneous by physico-chemical methods[2]. By a quantitative assay technique developed in our laboratory[3], it has been found to be two to three times as active as whole lyophilized bovine cord. Because of the high state of purity of the compound and its probable concentration in whole cord (1·6 per cent was isolated) it was concluded either that its activity was attenuated or that this compound alone could not account for the entire activity of whole lyophilized cord. Consequently, other less drastic extraction methods were investigated in an attempt to isolate a fraction with higher specific activity than the collagen-like protein.

The fraction used in our tests with Colover's tubercle bacillus fractions was a cold 5 per cent potassium chloride extract of partially defatted bovine spinal cord, which was approximately ten times as active as whole lyophilized cord when compared on a dry-weight basis, and thus five times as active as the collagen-like protein. It consisted mainly of protein with 1–2 per cent carbohydrate and no detectable

Table 1. Allergic Encephalomyelitic Activity of 'Purified' Fractions from Bovine Cord and Tubercle Bacillus

Tubercle bacillus fraction	Disease index* mean ± standard error
None	0 ± 0
0·25 mgm. whole *H37RV*†	7·9 ± 1·2
	8·4 ± 0·9
0·1 mgm. whole *H37RV*‡	7·1 ± 1·1
0·025 mgm. whole *H37RV*†	4·8 ± 1·3
0·1 mgm. Colover's 'crude' fraction	6·9 ± 1·4
0·02 mgm. Colover's 'crude' fraction	7·4 ± 1·8
0·1 mgm. Colover's 'purified' fraction (1/172)	3·2 ± 1·0
0·02 mgm. Colover's 'purified' fraction (1/172)	8·0 ± 1·0

The cord fraction was 0·02 mgm. *C–2–P* (5 per cent potassium chloride extract of partially defatted bovine spinal cord throughout).

* The disease index is a numerical evaluation of the severity of the disease reaction, based on combined clinical and histological data and the presence or absence of lipæmia. The scale is from 0 (no disease) to 10 (maximum reaction). The average of ten animals injected simultaneously is used for the disease index of a given weight of material. Maximum values for most fractions vary from 7 to 9, with a standard error of the mean of ± 1.

‡ Lyophilized. Kindly supplied by Dr. P. Y. Paterson, New York University, and National Institute of Allergy and Infectious Diseases, Laboratory of Immunology.

lipid. More detailed information regarding the chemistry and activity of this fraction will be published elsewhere[3,4].

The results, which confirm qualitatively those reported by Colover (see following communication), are reported in Table 1. With the particular dose of the spinal cord fraction used in these tests it would appear that about half-maximal disease is produced with 0·025 mgm. whole tubercle bacilli. Small enough doses of Colover's bacillary preparations have not yet been tested to determine their 50 per cent effective doses, but it is obviously less than 0·02 mgm. It is interesting that in our tests with his 'purified' material an inhibitory effect is observed with a relatively large dose (0·1 mgm.).

Table 1

Method (see text)	Tubercle bacillus fraction	Central nervous fraction	Result*
1	2 mgm. Residue 1/172 (ref. 1)	200 mgm. whole guinea pig brain	7/11
1	2 mgm. Wax *D* Canetti†	200 mgm. whole guinea pig brain	1/6

2	0·1 mgm. Purified residue 1/172	16 mgm. guinea pig brain	5/5
2	0·1 mgm. Wax *D* Canetti	16 mgm. guinea pig brain	4/5
2	1 mgm. Wax *D* Canetti	0·2 mgm. II-*B*	5/6
2	1 mgm. Wax *D* Canetti	0·2 mgm. 5 per cent potassium chloride extract of bovine spinal cord‡	6/6

* Numerator, number of animals with experimental allergic encephalitis; denominator, number of animals in the experiment.

† This material gave different results in methods 1 and 2.

‡ Kindly prepared and supplied by Dr. E. Roboz.

As our experience accumulates in testing various brain and cord fractions, we are more and more impressed by the necessity of testing every fraction at several different dose-levels. To our knowledge, the activity of the tubercle bacillus has never been studied quantitatively. For this reason, a quantitative comparison between these two fractions and the whole tubercle bacilli cannot be made. Freund (personal communication) found that with a dose of whole brain giving maximal reaction, 0·016 mgm. killed tubercle bacillus was near the lower limit of effectiveness. Our experiments indicate a similar lower level (0·02 mgm. killed tubercle bacilli).

The experiments reported are preliminary in the sense that the fractions tested, with the exception of the collagen-like protein from bovine cord, are not pure compounds. The crucial experiment remains to be done—the production of the disease with two pure chemical compounds. The present results indicate that this goal will eventually be realized, since it has been shown that neither whole nerve tissue nor whole tubercle bacillus is an absolute requirement for the production of allergic encephalomyelitis.

Experimental Allergic Encephalomyelitis induced with Combined 'Purified' Spinal Cord and Bacillary Fractions

IT has previously been reported by Colover and Consden[1] that residues made from heat-killed human tubercle bacilli which had been subjected to serial chemical procedures still retained the capacity to produce experimental allergic encephalomyelitis in guinea pigs when combined with homologous brain by the method (method 1, Table 1) described by Colover[2]. As a result of the kindness of Dr. Marian W. Kies, of the U.S. National Institute of Mental Health, a sample of 'collagen-like protein II-*B*'[3] prepared from bovine spinal cord by Dr. E. Roboz was made available for trial with this bacillary residue (1/172)[1]. An emulsion was made so that each ml. contained: 0·5 mgm. bacillary residue 1/172; 0·4 ml. 'Bayol *F*'; 0·2 ml. 'Falba'; 0·4 ml. normal saline; 0·2 mgm. collagen-like protein II-*B*. This latter fraction was used as a substitute for the 50 mgm. of heated brain emulsion previously used[1]. Eight guinea pigs were injected with 1 ml. of emulsion at weekly intervals between the scapulæ intramuscularly, each animal receiving four injections. Three became severely paralysed and died just before the thirtieth day; the remainder were killed on the fortieth day. On histological examination five animals showed the typical lesions of experimental allergic encephalomyelitis, and another animal showed a large intradural granuloma. The extent of the lesions was less than when 50 mgm. of heated brain emulsion per ml. were used as the brain factor. Six control animals were similarly treated except for the omission of the bacillary factor from the injected material. Three were killed at 30 days and three at 40 days. None showed neurological signs, but one showed an isolated focus of microglial reaction in one cerebral hemisphere histologically.

Kies, Alvord and Roboz (see previous communication), using a different technique, mixed a sample of the same purified bacillary residue prepared by Colover and Consden with another bovine spinal cord protein prepared by extracting the cord with 5 per cent potassium chloride after preliminary defatting, and have found this mixture was active in producing experimental allergic encephalomyelitis in guinea pigs.

Previous attempts by Colover and Consden[1], Colover[2,4], were negative when various wax fractions of tubercle bacilli were combined with homologous whole brain. Positive results with wax fractions had been obtained[5,6], and in view of this a further trial was made with wax *D* Canetti prepared by Dr. J. Asselineau and kindly supplied by Dr. E. Lederer, containing similar components to those present in the residue 1/172 (Lederer, E., personal communication). The method of injection (method 2, Table 1) differed from that described above (method 1) in that single injections of 0·2 ml. of the following emulsions were injected into the dorsum of the hind foot of guinea pigs: 1 or 0·1 mgm. bacillary fraction; 0·085 ml. 'Bayol *F*'; 0·015 mgm. 'Arlacel *A*'; 0·1 ml. saline; 16 mgm. of whole guinea pig brain or 0·2 mgm. bovine spinal cord fraction.

Table 1 shows that by this method homologous whole brain and both bovine spinal cord fractions were effective with wax *D* Canetti.

The results reported here and by Kies, Roboz and Alvord in the previous communication confirm that experimental allergic encephalomyelitis can be produced in guinea pigs by emulsions containing only relatively small fractions of acid-fast bacilli and central nervous tissue, and show that either of two constituents of tubercle bacilli (residue 1/172 and wax *D* Canetti) mixed with either of two bovine spinal cord protein fractions can be effective.

I would like to thank the Medical Research Council for a grant towards this work.

Note added in proof. Since the submission of this paper it has been found that 1 mgm. of chromatographically pure wax *D* Canetti (E. Lederer), which is a pure compound, combined with fraction II-*B* produces a high incidence of experimental allergic encephalitis in guinea pigs.

SYNTHETIC POLYPEPTIDE SUBSTITUTES FOR GELATIN IN PHOTOGRAPHIC EMULSIONS AND OBSERVATIONS ON GELATION

By Dr. H. W. WOOD
Ilford Research Laboratory, Ilford, Ltd., London

THE synthesis of water-soluble ampholytic polypeptides has been undertaken with the view of simulating those properties of gelatin which are involved in the preparation of photographic emulsions. Two attributes will be discussed here. The first, of specialized interest, is the ability to promote the growth of flat, well-shaped silver halide grains during the process of physical ripening. Many of the colloids which have been proposed as substitutes for gelatin, for example polyvinyl alcohol, are not able to do this. It seemed at one time that a polypeptide structure was obligatory; but recently, it has been found that certain polyethylene oxides are effective[1]. It is now shown that the required kind of grain-growth can be achieved with synthetic polypeptides. The work also permits some observations on the other important property of gelatin, one which is of wider interest, namely, gelation. The two attributes under consideration, control of grain-growth and gelation, are not necessarily so diverse in origin as would at first appear, because the former probably relies partly on those intermolecular links which are formed, to a much greater extent, in a gel.

Ampholytic polypeptides have been synthesized by a method, now well known, in the following two stages. (1) Co-polymerization of Leuchs's anhydrides in dioxan with ammonia as catalyst; the main components were the anhydrides of γ-methyl glutamate and ε-N-carbobenzyloxylysine. (2) Removal of side-chain protective groups to give water-soluble polypeptides containing glutamic acid and lysine.

Polypeptides which would control grain-growth in the manner required resulted when highly purified intermediates and controlled amounts of initiator were used at the polymerization stage. Only in this way may compounds of high molecular weight be obtained, according to Blout *et al.*[2]. The observations of the latter in respect of the polymerization of γ-methyl-L-glutamate anhydride have been confirmed. When prepared by the method of Hanby *et al.*[3], γ-methyl glutamate itself was found to contain persistent traces of glutamic acid which could not be removed except by an anion-exchanger. The corresponding Leuchs's anhydride, after several recrystallizations, had m.p. 104° as against the reported values of 96–97°[2] and 99–100°[3]. Polymethyl glutamate prepared from this had η_i (in dichloracetic acid) = 1·32. Referred to data of Doty *et al.*[4] on the benzyl ester, this represents a molecular weight of about 200,000. Previous samples of the polypeptide from not specially purified anhydride had $\eta_i \sim 0{\cdot}1$. For the other main component, DL-lysine was used, as it was not found possible to purify L-lysine (natural origin) satisfactorily. The pure ε-N-carbobenzyloxylysine anhydride had m.p. 110°.

Co-polymers have been prepared from the above two anhydrides in various proportions, alone and admixed with proportions of another neutral amino-acid anhydride, namely, glycine, phenylalanine, cystine, proline or sarcosine. Elementary analyses of the products were in good agreement with expectation based on a long chain (so that end groups can be ignored). Discrepancies previously noted[5] may perhaps be ascribed to chain-branching and termination reactions, due to an excess of initiators in the intermediates.

Water-soluble polypeptides (stage *b*), co-polymers of glutamic acid and lysine alone or with the other amino-acids mentioned, were prepared by mild treatment of the above with hydrogen bromide in acetic acid, followed by precipitation with ether and dissolution in weak alkali. The last operation was facilitated by the presence of proline or sarcosine, presumably because of the reduced tendency to form intermolecular linkages on the peptide nitrogens which, with these two amino-acids, do not have a

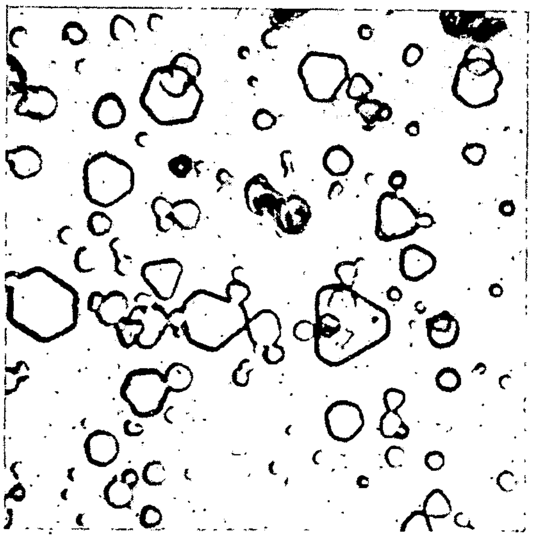

Fig. 1. Photomicrograph of silver iodobromide grains grown in the presence of a polypeptide of expected formula $Glu_4Lys_3Sar_3Cys_{0.1}$. No other colloid was present at any time during the preparation of the emulsion or slide. (× 2,500)

hydrogen substituent. This observation was useful when dissolving polypeptides containing cystine, the disulphide group of which is very sensitive to alkali. The products were isolated from the neutralized aqueous solutions by precipitation with alcohol and, in this respect, resembled gelatin. They are in general freely soluble in water at all pH-levels. Although polyglutamic acid itself is insoluble in water, a minor amount (20 per cent) of lysine in the co-polymer is sufficient to prevent precipitation. Glutamic acid is less effective at the other end of the scale and co-polymers with relatively large proportions of lysine ($>$ 80 per cent) are insoluble at high pH.

Flat, well-shaped silver halide grains have been grown in many of the polypeptides prepared, including those containing only glutamic acid and lysine. The composition is not critical, nor does it need to be complex. In support of this, it may be mentioned that grain-growth has also been produced using the soluble form of silk fibroin[6], a protein with a simpler amino-acid structure than gelatin. The important point is that the required grain growth was only achieved when pure intermediates had been used. From the above data on polymethylglutamate it is believed (though not proved) that the result is indicative of high molecular weights. An example of silver halide grains ripened in the presence of one of the water-soluble polypeptides is shown in Fig. 1.

None of the polypeptide solutions at any pH or concentration-level gave true gels. The nearest approach was with compounds containing large amounts of lysine, which gave gelatinous precipitates at high pH. Some observations have been made relative to the hypothesis of Grabar *et al.*[7] that gelation depends on the presence of arginine units in gelatin. The hypothesis rests on the fact that the power to gel is destroyed by hypobromite, a reagent known to disrupt guanidino groups. The matter has been further studied by Davis[8], and Janus[9] has found that guanidation of gelatin increases gel rigidity. The chemical effect of guanidating gelatin has been analysed by Eastoe *et al.*[10].

Polypeptides containing glutamic acid with ornithine or lysine have been treated with O-methylisourea at pH 10. This reagent converts ornithine to arginine and lysine to homoarginine. (Polyarginine has previously been prepared along these lines by Katchalski *et al.*[11].) The products were again isolated by alcohol precipitation of the neutralized solutions. The completeness of the guanidation could be checked conveniently by paper electrophoresis of hydrolysates. In phthalate buffer at pH 6, the mobilities towards the cathode of arginine and homoarginine are the same, as are those of ornithine and lysine; the ratio of the mobility of the first pair to that of the second is 0·85. Ornithine may thus be separated from arginine or lysine from homoarginine in a few hours. Glutamic acid moves away in the direction of the anode.

Guanidation of the polypeptides did not introduce the ability to gel. (The properties as regards control of grain-growth were also unaffected.) The result suggests that the arginine unit of gelatin does not play the decisive part in gelation, envisaged by Grabar *et al.* It seems likely that the reagent used by the latter will destroy or brominate important groups other than guanidino; for example, peptide. The effect of blocking the nitrogen of the peptide groups is seen in polypeptides containing sarcosine, which are not only easier to convert to the soluble form (cf. above) but give much less viscous aqueous solutions, implying reduced molecular interaction.

Just as this account had been completed, a communication appeared emphasizing the importance of peptide groups: in it, Bello *et al.*[12] show that gelation is inhibited by forming copper-peptide complexes.

Some success having been achieved in the aim of simulating the properties of gelatin, as regards control of grain-growth, with essentially simpler synthetic polypeptides, it is proposed to continue the search for the gelling factor(s). Clearly, something other than a polypeptide backbone is required in the molecule. In view of its unique occurrence in collagenous proteins, hydroxyproline (not yet incorporated in the present polypeptides) is of obvious interest. A more remote possibility is that the polysaccharide 'impurity' of gelatin[13] is important. If a particular sequence of amino-acid residues is involved, the present synthetic method is unlikely to be useful. It has long been known that side-chain polar groups do not play an important part in gelation, since the latter is not dependent upon pH[14]. The main function of these groups in the polypeptides is to confer solubility in water.

Thanks are due to Messrs. D. J. Farmery and J. P. Johnson for technical assistance and to the Directors of Ilford, Ltd., for permission to publish this communication.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

Lung Cancer and Cigarettes?

THE association observable between the practice of cigarette smoking and the incidence of cancer of the lung, to which attention has been actively, or even vehemently, directed by the Medical Research Council Statistical Unit, has been interpreted, by that Unit, almost as though it demonstrated a causal connexion between these variables.

The suggestion[1], among others that might be made on the present evidence, that without any direct causation being involved, both characteristics might be largely influenced by a common cause, in this case the individual genotype, was indeed rejected with some contempt by one writer[2], although I believe that no one doubts the importance of the genotype in predisposing to cancers of all types.

It seemed to me that although the importance of this factor had been overlooked by the Unit in question, it was well within the capacity of human genetics, in its current state, to examine whether the smoking classes to which human beings assign themselves, such as non-smokers, cigarette smokers, pipe smokers, cigar smokers, etc., were in fact genotypically differentiated, to a demonstrable extent, or whether, on the contrary, they appeared to be genotypically homogeneous, for only on the latter view could causation, either of the disease by the influence of the products of combustion or of the smoking habit by the subconscious irritation of the postulated pre-cancerous condition, be confidently inferred from the association observed.

The method of inquiry by which such differentiation can be recognized is the same as that by which the congenital factor has been demonstrated for several types of disease[3], namely, the comparison of the similarities between monozygotic (one-egg) and dizygotic (two-egg) twins respectively; for any recognizably greater resemblance of the former may be confidently ascribed to the identity of the genotypes in these cases.

I owe to the generous co-operation of Prof. F. von Verschuer and of the Institute of Human Genetics of the University of Münster the results of an inquiry into the smoking habits of adult male twin pairs on their lists.

The data so far assembled relate to 51 monozygotic and 31 dizygotic pairs, from Tübingen, Frankfurt and Berlin. Of the first, thirty-three pairs are wholly alike qualitatively, namely, nine pairs both non-smokers, twenty-two pairs both cigarette smokers and two pairs both cigar smokers. Six pairs, though closely alike, show some differences in the record, as in a pair of whom one smokes cigars only, whereas the other smokes cigars and sometimes a pipe. Twelve pairs, less than one-quarter of the whole, show distinct differences, such as a cigarette smoker and a non-smoker, or a cigar smoker and a cigarette smoker.

By contrast, of the dizygotic pairs only eleven can be classed as wholly alike, while sixteen out of thirty-one are distinctly different, this being 51 per cent against 24 per cent among the monozygotics.

The data can be rearranged in several ways according to the extent to which attention is given to minor variations in the smoking habit. In all cases, however, the monozygotic twins show closer similarity and fewer divergencies than the dizygotic.

There can therefore be little doubt that the genotype exercises a considerable influence on smoking, and on the particular habit of smoking adopted, and that a study of twins on a comparatively small scale is competent to demonstrate the rather considerable differences which must exist between the different groups who classify themselves as non-smokers, or the different classes of smokers. Such genotypically different groups would be expected to differ in cancer incidence; and their existence helps to explain such oddities as that pipe and cigar smokers should show much less lung cancer than cigarette smokers, while among the latter, the practice of inhaling is associated with less rather than with more cancer of the lung.

Dr. Bradford Hill, while admitting that the evidence of association found by his Unit did not amount to proof of causation, has emphasized that he does not know what else it can be due to. The facts here reported do show, however, that the choice is not so narrow as has been thought.

Measurement of Toughness in Cold-stored Fish

LUIJPEN recently noticed[1] that the proportion of fish muscle protein that would dissolve in 5 per cent sodium chloride solution was not correlated with the development of toughness during cold-storage at or below $-20°$ C. The discovery was of great significance to the study of cold-storage phenomena, because it implied that the soluble protein nitrogen (usually expressed as a percentage of the total protein nitrogen) could not now be used as an objective standard for the quality of cold-stored fish. This was contrary to former belief.

It seems likely, therefore, that future investigations of freezing and cold-storage of fish will require the direct estimation of toughness as a measure of quality change. A satisfactory method for measuring toughness does not, however, exist at present. Assessment by a taste panel is time-consuming and inaccurate, and can only deal with a few samples at a time. Machines such as penetrometers, various types of shear apparatus, etc., which successfully estimate the toughness of beef muscle, are not as a rule adaptable to fish because the fibres in the latter case are extremely short and interspersed with sheets of connective tissue (myocommata) which are tougher than the muscle itself.

The following method, which requires only a small piece of fish muscle, was therefore devised. It has so far been tried out only on uncooked cod (*Gadus callarias* L.).

A handle was made to hold two Swann–Morton No. 24 scalpel blades 3 mm. apart and parallel. By means of a gentle sawing action, the blades were sunk into a wide myotome (muscle segment) on the 'bone' side of the fillet, at right angles to the long

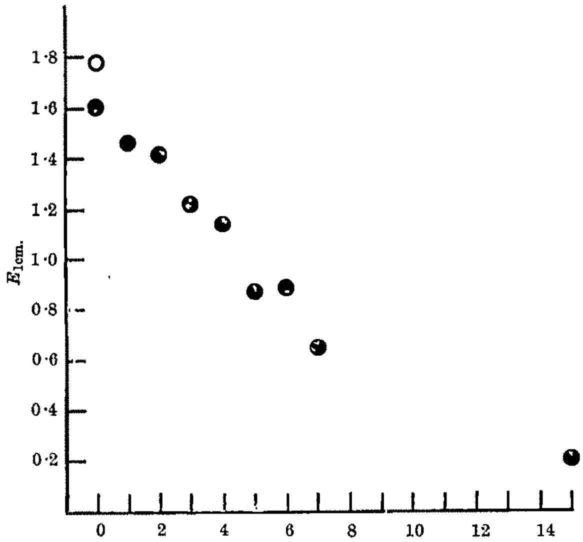

Fig. 1. Optical density of brei obtained by homogenizing muscle from cod fillets, frozen in 12 hr. and stored, wrapped, at −14° C. for different times. Each point is the average for thirty fillets determined in duplicate. ○, Fresh muscle before freezing; ●, frozen and thawed

axis, in the block of muscle lying immediately dorsal to the lateral line. The 'double scalpel' was then withdrawn with a slight twisting movement, so that a piece of muscle containing fibres of uniform length became detached from the fish and could be poked out from between the blades. It was freed from any traces of connective tissue, and two aliquots, each of 200 ± 5 mgm., were weighed out on a torsion balance.

20 ml. of approximately 1 per cent formaldehyde solution were used to fill the metal cup of a Marsh–Snow homogenizer[2] which had been fitted with a baffle plate just above the paddle blade to prevent frothing. The weighed sample was added to this, and the homogenizer run for 20 sec. at about 2,200 r.p.m. It was important not to put the tissue in before the formaldehyde. The resulting homogenate was poured with minimum delay into a ½-cm. optical cell, and the optical density read immediately with a photometer. The wave-length of the incident light was selected so that the readings were conveniently placed on the scale of the photometer. In the present experiments a 430 mμ filter with a Hilger 'Biochem' absorptiometer was satisfactory. It was important to avoid any trace of frothing, and in this connexion the formaldehyde was kept below 20° C., being most satisfactory when cooled below 10° C. before the start of the experiment.

It was observed that the fibres from fresh fish muscle were completely broken up by this treatment, making an optically dense 'soup'. Frozen fish showed an increasing proportion of intact fibres in the brei as the storage time increased, until eventually only intact fibres were found, suspended in clear liquid which let through much more light. The optical density in the intermediate stages decreased regularly according to the number of intact fibres present.

Microscopic examination of breis from fish of intermediate toughness showed that, while a few fibres appeared to have been split longitudinally[3], the majority were either completely dispersed as fine fibrils or completely intact. This seems to show that 'toughness' is related to the cell envelope, destruction of which releases all the fibrils, which it would not do if the cells as a whole were becoming tougher.

Fig. 1 shows the changes in texture of frozen cod fillets, as measured by the new method, that occurred during cold storage at −14° C. It will be seen that freezing itself increased toughness and that the fish then became progressively tougher during subsequent storage. The immediate effect of freezing can usually be detected qualitatively by a taste panel, but as a rule it is not possible to measure subsequent changes in texture with any precision by this means.

We would thus seem to have a satisfactory method for assessing the texture of frozen fish. There are several possible factors such as the effects of the size of the fish and the treatment before freezing, manner of freezing, etc., which have not yet been examined. As these would be genuine changes in texture, however, they would not affect the validity of the results, but only their interpretation.

It is hoped to publish a full report of these investigations elsewhere.

I am indebted to Mr. Harry Bruce, who made the homogenizer and the special scalpel, and to Miss Eleanor Brown for technical assistance. The work described is part of the programme of the Food Investigation Organization of the Department of Scientific and Industrial Research.

Hexokinase Activity in Cell-free Extracts of *Leishmania donovani*

Leishmania donovani, the protozoan organism causing visceral leishmaniasis, is known to utilize glucose and other carbohydrate substrates for its continued metabolic activity. The evidence available, however, does not show whether phosphorylation plays a direct or an indirect part in the utilization of carbohydrates by this organism. During an investigation into the mechanism of utilization of various carbohydrates by *L. donovani*, strong hexokinase activity has been detected in the cell-free extracts of this organism. *L. donovani*, strain 81, cultured on Ray's medium[1] at 24° C. and recycled every three weeks from the N.N.N. medium, was used in this study. After growth for three days on Ray's medium, the organism was scraped from the surface of the agar, washed once with ice-cold isotonic saline and ground with glass powder, with gradual additions of ice-cold isotonic saline. Isotonic potassium chloride in place of sodium chloride was found to be equally satisfactory. The crushed suspension was centrifuged at 3,000 r.p.m. for 5 min. and the supernatant was used as crude enzyme extract.

Hexokinase activity has been followed by three different methods: (*a*) the manometric method of Colowick and Kalckar[2], (*b*) measurement of disappearance of free sugar by Nelson's method[3] and (*c*) the phosphorus-balance method, measuring the utilization of acid-labile phosphate and the concomitant formation of esterified phosphate.

Standard conditions for the assay of the hexokinase activity were as follows: 3·0 ml. of the complete reaction mixture contained 10 μmoles of substrate, 20 μmoles of the sodium salt of adenosine triphosphate, 10 μmoles of magnesium sulphate, 180 μmoles of sodium fluoride, 30 μmoles of sodium bicarbonate (*p*H 7·4), 1 cm.^{3} of enzyme extract containing 0·3–0·35 mgm. total nitrogen. Incubations were carried out in conventional Warburg manometric vessels at 37° C. in an atmosphere of 95 per cent nitrogen and 5 per cent carbon dioxide.

The rate at which carbon dioxide was evolved from the bicarbonate buffer, after due corrections for any adenosine triphosphatase and other non-specific activities destroying adenosine triphosphate, gave an approximate measure of the hexokinase activity. For measuring the amount of sugar utilized due to the hexokinase activity, aliquots of the samples at different time intervals were treated with barium hydroxide and zinc sulphate, using Somogyi's method[4], and the free reducing sugars were analysed by Nelson's method[3]. A control experiment was carried out without adenosine triphosphate and the activity was expressed on the basis of net difference in free glucose over the control. Acid-labile phosphate was determined by estimating the inorganic phosphate released after heating an aliquot with 1 *N* hydrochloric acid at 100° C. for 7 min. Esterified phosphate was estimated from the difference in the amount of adenosine triphosphate used up and the inorganic phosphorus liberated during incubation. Phosphorus estimations were done by Fiske and Subbarow's method[5]. All the sugars used in this study were of *dextro*-varieties.

Typical rates of output of carbon dioxide in the presence of different sugars are shown in Table 1. In the case of *d*-glucosamine, no correction was made, however, for its acid-binding power in the present experimental conditions. From the relative phosphorylation-rates given in Table 1, it will be noted that the hexokinase activity in the cell-free extracts of this protozoal organism is very marked towards glucose, fructose, mannose and *d*-glucosamine, whereas with galactose, glycerol and ribose the activity seems to be a little weaker. The presence of such an active glucosamine-phosphorylating enzyme suggests that this amino-sugar may play some important part in the metabolism of *L. donovani*. In order to characterize the substrate specificity of this hexokinase, some preliminary experiments were carried out, using mixtures of hexoses and *d*-glucosamine, on the rate of phosphorylation. The results indicate that for glucose, fructose, mannose, galactose and *d*-glucosamine a single hexokinase enzyme may be involved, since there is a mutual inhibitory effect on the rate of glucose phosphorylation in presence of either fructose, galactose, mannose or *d*-glucosamine. This inhibition may apparently be due to competition of all the substrates for the common enzyme involved. In this respect the protozoal enzyme has some similarity with yeast and brain hexokinases[6].

Table 1. PHOSPHORYLATION OF DIFFERENT SUGARS BY CELL-FREE EXTRACTS OF *L. donovani*

Substrate used (0·01 *M*)	Carbon dioxide liberated (μl.) at different time intervals (min.)					
	5	10	15	20	25	30
Glucose	20	38	53	63	70	75
Fructose	21	40	54	63	71	78
Mannose	16	30	43	51	58	64
Galactose	8	14	18	22	25	27
d-Glucosamine	16	32	47	59	69	74
Glycerol	5	3	1	—	—	—
Ribose	4	2	1	—	—	—

Table 2. PHOSPHORYLATION OF GLUCOSE BY EXTRACTS OF *L. donovani*

Exp. No.	Glucose disappearance (μmoles)	Carbon dioxide evolved (μmoles)	Adenosine triphosphate used (μmoles)	Esterified phosphate formed (μmoles)
1	2·9	3·0	14·0	2·4
2	3·0	3·5	13·0	2·8
3	3·2	3·5	12·8	3·0

The results in Table 2, illustrating three typical experiments carried out for half an hour under standard experimental conditions, suggest that there is a fairly close stoichiometric balance between the amount of glucose utilized and the amount of esterified phosphate formed, most of which was found in combination with fructose.

A number of substances, such as *p*-chloromercuric benzoate, αα′-dipyridyl, iodoacetate (used at 10^{-4} *M* concentrations), were found to have a very small inhibitory effect on the activity of this enzyme. The activity of the enzyme extract was not improved by additions of cysteine or glutathione. These findings indicate that the hexokinase enzyme of *L. donovani* is not markedly dependent upon functional —SH groups for its activity.

Details regarding the substrate specificities, substrate affinities, *p*H optima and co-factor requirements of this enzyme will be published elsewhere.

Effect of Larval Brain on the Imaginal Differentiation in the Silkworm

I HAVE shown earlier[1,2] that, in *Bombyx mori*, pupal brain has a function which brings about imaginal differentiation, probably by affecting the prothoracic gland in the pupa, and that the mode of action by which the prothoracic gland is influenced is hormonal in nature. Kobayashi and Kirimura[3] attempted to extract the hormone and succeeded in obtaining an oily substance which is effective in bringing about imaginal differentiation in the 'Dauer-pupæ' from the extract of the pupal brain.

It has not yet been established, however, whether the larval brain has the same function in imaginal differentiation as the pupal brain. Accordingly, I have investigated this problem by implanting larval brain into the head of 'Dauer-pupa' of *Bombyx mori.*

The larvæ of the F_1 hybrid between two races, *J*115 and *C*108, were used as donors of brain and the 'Dauer-pupæ' of the hybrid between two races, *J*122 and *C*115, were used as recipients.

Brains to be tested were removed from the 5th instar larvæ on the fourth day after the fourth moult.

Table 1. EFFECT OF IMPLANTATION OF A FRESH LARVAL BRAIN INTO EACH 'DAUER-PUPA' AT 25° C.

No. of 'Dauer-pupae' used as recipient	No. of dead individuals	No. of moths emerged	Days from implantation to emergence
15 (♀)	1	14	18–25*

* Mean time from implantation to emergence, 20 days.

A fresh brain was implanted into the head of each 'Dauer-pupa', the 'Dauer-pupæ' having been kept at 25° C. for 30 days after being deprived of their brains immediately following pupation. After the implantation, the pupæ were kept at 25° C.

As shown in Table 1, 14 out of 15 pupæ operated became moths during the period from the eighteenth to the twenty-fifth day after the implantation and one died after five days. No imaginal differentiation was observed in 15 'Dauer-pupæ', in which no brain had been implanted although they were kept at 25° C. for 100 days after pupation.

It is concluded that the larval brain is as effective as the pupal brain in the imaginal differentiation of 'Dauer-pupa'.

In silkworm pupa, the brain hormone is elaborated in the neurosecretory cells of the brain and is released into the blood stream[2]. On the other hand, in the 4th and 5th larval stage the neurosecretory materials elaborated in the neurosecretory cells of the brain were released through two paths, one from the cell to the nervi corporis cardiaci through the axon of the *A*-cell, and the other from the cell to the blood stream through the cortex of the brain[2]. It is highly probable, therefore, that the secretory material released through the latter path is the brain hormone concerned with imaginal differentiation.

Thus it appears that even in the larval stage the secretion of the brain affects the prothoracic gland in *Bombyx mori*.

A Correlation between the Compositions of Deoxyribonucleic and Ribonucleic Acids

WE have shown that the composition of the ribonucleic acid of bacterial cells does not depend upon the very considerable changes in composition of deoxyribonucleic acid found when profound reorganizations of the hereditary nature of intestinal bacteria occur[1,2]. The composition of deoxyribonucleic acid in different bacterial species belonging to various systematic groups was shown to vary widely (from the extreme *AT*-type to the highest *GC*-type); whereas that of ribonucleic acid from these species was shown to vary slightly, small differences being noted only between very diverse species[3,4]. Thus the greater part of the ribonucleic acid of the cell appeared to be independent of the deoxyribonucleic acid.

However, a certain correlation was found to exist. This correlation is expressed in a tendency towards an increase in the ratio $\frac{G+C}{A+U}$ in ribonucleic acid when passing from the species with the smaller $\frac{G+C}{A+T}$ ratio in their deoxyribonucleic acid to those with greater values of this ratio[4].

We have studied the composition of the two nucleic acids applying methods[1] based on the mild alkali hydrolysis of the total bacterial mass (after removing acid-soluble substances) by means of a modified form of the method of Schmidt and Thannhauser. The composition of the ribonucleic acid was determined by paper chromatography of nucleotides; the composition of the deoxyribonucleic acid was determined by paper chromatography of bases. The eluates of spots were examined in the ultra-violet with a quartz spectrophotometer. Each result represents the mean of at least four single determinations in each of two parallel hydrolysates for each culture. The mean error of the mean values for nucleotides and bases presented in Tables 1 and 2 was not greater than 2 per cent. In both tables the species

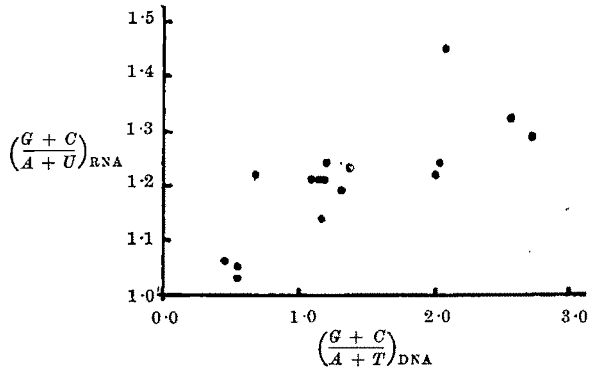

Fig. 1

are arranged in order of increase of the ratio $\frac{G+C}{A+T}$ in their deoxyribonucleic acid. The details have been published elsewhere[4].

The correlation is shown in Fig. 1, where the values of $\left(\frac{G+C}{A+T}\right)_{\text{DNA}}$ are plotted against those of $\left(\frac{G+C}{A+U}\right)_{\text{RNA}}$, each point corresponding to a species having characteristic values of the two ratios. There appears to be a positive correlation between the ratios $\left(\frac{G+C}{A+U}\right)_{\text{RNA}}$ and $\left(\frac{G+C}{A+T}\right)_{\text{DNA}}$ for the nineteen bacterial species studied; the correlation coefficient is 0·72, with a mean error of 0·17; that is, $r = +0{\cdot}72 \pm 0{\cdot}17$. The correlation coefficient is thus 4·3 times as large as its mean error.

The fact that the value of regression of $\left(\frac{G+C}{A+U}\right)_{\text{RNA}}$ on $\left(\frac{G+C}{A+T}\right)_{\text{DNA}}$ is very small explains why one encounters difficulties in studying the differences in composition of the ribonucleic acid of species differing drastically in the composition of their deoxyribonucleic acid.

It should be noted that the positive correlation between the compositions of the two nucleic acids has been established for only nineteen species of bacteria: further investigations are therefore necessary to show that this correlation is not fortuitous.

Nevertheless, our results suggest that part at least of the ribonucleic acid of the cell depends on the deoxyribonucleic acid, and that the two nucleic acids may even be similar with respect to their base compositions. On the other hand, the small value of the regression indicates that the greater part of the cell ribonucleic acid is relatively independent of the deoxyribonucleic acid.

A Possible Mechanism for the Initial Transfer of the Genetic Code from Deoxyribonucleic Acid to Ribonucleic Acid

IT is now a generally accepted hypothesis that deoxyribonucleic acid contains the genetic information in the living cell which ultimately directs the formation of protein. Moreover, there is some evidence that deoxyribonucleic acid acts as a template for the formation of ribonucleic acid which relays information to the protein polypeptide chain by another template mechanism. If this were so there should be a simple relation between the composition of ribonucleic and deoxyribonucleic acids, since there are only four commonly occurring base groups in each nucleic acid. The fact that this is not so is probably due to two factors: only a fraction of the nucleic acid in the cell functions as a template and, therefore, only this fraction would be pertinent when comparing base ratios of the two nucleic acids; there are several different templates (more than two) involved in the transfer of information from deoxyribonucleic acid to the polypeptide chain, and, as a result the general problem of information transfer might be more easily solved by consideration of each template and its immediate chemical product.

As an example of this approach, consider the relation between the two nucleic acids and concentrate on the ribonucleic acid that is most likely to be produced directly on the deoxyribonucleic acid. I shall assume that this is nuclear ribonucleic acid because of its close cytological connexion with deoxyribonucleic acid. Furthermore, a good deal of evidence has accumulated that the cell nucleus plays a crucial part in the metabolism of ribonucleic acid[1].

This limitation makes it difficult to test any coding mechanism because of the paucity of pertinent data, for example, the base composition of deoxyribonucleic acid and nuclear ribonucleic acid. Nevertheless, I wish to propose the following code because it suggests further experiments. The data presented in Table 1 are taken from the results of Chargaff[2] and Vincent[3].

Since deoxyribonucleic acid and ribonucleic acid are each associated with four types of base groups, one might expect to find an immediate one-to-one correspondence between their respective bases. Chargaff's data do not verify this expectation however, and such a scheme is immediately discounted. The problem of finding four specific sites on deoxyribonucleic acid for binding ribonucleic acid has a possible solution resulting from the helical character of the duplex of the former which, in effect, gives rise to different binding sites being associated with a given nucleotide base-pair depending upon which polynucleotide chain the individual nucleotide members are situated. Thus adenine on chain I paired with thymine on chain II would make a different site from adenine on chain II and thymine on chain I. These two sites are designated as $A - T$ I and $A - T$ II. Likewise the other two sites are designated $G - C$ I and $G - C$ II. In this code each deoxyribonucleic acid base-pair functions as a location for one ribonucleic acid base-group in a single chain, the sequence of base-groups in the latter being determined by the sequence of base-pairs in the former acid. The particular correspondence I would like to suggest is shown in Table 2.

(1) This code predicts a necessary relation between the base composition of the two nucleic acids such

Table 1

Source of ribonucleic acid	Nuclear ribonucleic acid A/U	G/C	Pu/Py	$G+U/A+C$	$G+C/A+U$	Deoxyribonucleic acid $A+T/G+C$	Cytoplasm ribonucleic acid $G+C/A+U$
Rat liver	0·85	0·88	0·86	1·00	1·26	1·33	1·59
Ox liver	0·81	0·87	0·83	1·01	1·28	1·25	1·59
Ox kidney	0·99	0·88	0·83	0·94	1·26	1·30	1·52
Starfish oocyte	1·47	1·34	1·38	1·04	1·74	1·78	1·42

Abbreviations: A, adenine; G, guanine; C, cytosine; U, uracil; T, thymine; Pu, purines; Py, pyrimidines.

that the ratio $\frac{A+T}{G+C}$ of the deoxyribonucleic acid should be equal to the ratio $\frac{G+C}{A+U}$ of the ribonucleic acid. Reference to columns 6 and 7 in Table 1 giving the nucleotide compositions indicates that this relation holds. Two other relations for base ratios produced by this code depend on the relative composition of the individual deoxyribonucleic acid chains: (2) The 6-amino/6-keto ratio of ribonucleic acid depends upon the relative purine/pyrimidine ratio of the two deoxyribonucleic acid chains and is equal to one when both these chains contain the same relative amounts. (3) The purine/pyrimidine ratio of the ribonucleic acid depends upon the relative 6-amino and 6-keto content of the two deoxyribonucleic acid chains and is equal to 1 when these two chains contain the same relative amounts. From Table 1 we see that the relevant ribonucleic acid base ratios are not far from 1, although the 6-keto/6-amino ratio seems much closer to 1. It should be noted that I have not specified to which deoxyribonucleic acid chains I and II refer, and also that the code could be altered by interchanging the assignments for $A - T$ I and $A - T$ II (a template model has been built which would suggest that if the general code described here is correct, the assignments for $A - T$ I and $A - T$ II in Table 2 should be interchanged). This would have the effect of interchanging relations 2 and 3. In view of the fact that we have no data on the relative composition of the two chains we have no reason for preferring one system to the other. Moreover, there are so few data relevant to the proposal made here that we cannot be confident that the correlation found is general.

Table 2

DNA base pair	RNA base determined
A–T I	guanine
A–T II	cytosine
G–C I	uracil
G–C II	adenine

Work is in progress in this Research Unit to test the proposed code.

Catechol Amine Depletion in the Rat's Denervated Adrenal Gland following Chronic Administration of Reserpine

RECENT observations have indicated that reserpine can depress not only 5-hydroxytryptamine, but also noradrenaline- and adrenaline-levels in brain, heart, spleen and other sympathetically innervated tissues[1-3]. The depletion of adrenal medullary hormones by single doses of reserpine has been attributed to a stimulation of centres in the central nervous system, since spinal transection at T_1 is reported to prevent this response[1].

In the present study the effects of chronically administered reserpine ('Serpasil') on the catechol amine content of the denervated and innervated adrenal glands of the rat have been investigated. Male litter mates, weighing approximately 250–300 gm. were used throughout. The left adrenal gland was denervated aseptically, approximately 7–10 days prior to the administration of reserpine. The reserpine was given intraperitoneally in a dose of 0·1 mgm./100 gm. for a period of 5 days. The control group of animals received a placebo which consisted of the reserpine diluent. The catechol amine content of the glands was extracted at 4° C. in a glass homogenizer using 5 per cent trichloracetic acid. The acid was removed by washing the extract with 3 volumes of peroxide-free diethyl ether[4]. Bio-assay was performed using the cat's blood pressure in a preparation which had been pretreated with hexamethonium, atropine and diphenhydramine[5]. Total catechol concentrations were obtained in noradrenaline equivalents. All results were subjected to set or paired comparisons using the t-ratio for the determination of statistical significance.

A marked depression in catechol amine-levels was obtained in both the denervated and innervated glands after the administration of reserpine for 5 days (Table 1). A comparison with placebo-treated controls indicated that this depletion was of a high order of significance (Table 2; 1, 2). The innervated and denervated glands in each of the two experimental groups when subjected to a paired comparison revealed no significant differences (Table 2; 3, 4). This suggests that reserpine may deplete the denervated gland to about the same degree as the innervated one.

These results demonstrate that the depleting action of reserpine on medullary amines may occur in the

absence of any direct neural connexion with the central nervous system.

Since chronic reserpine administration causes the release of both noradrenaline and adrenaline from the rat's adrenal gland and does not apparently impede the normal rate of re-synthesis of these substances (ref. 6 and B. L. Mirkin, unpublished results), it is probable that the peripheral effect which has been observed is due to some action on those mechanisms which regulate the storage and release of catecholamines from the adrenal medulla. This aspect of the problem is at present under investigation.

This work was supported by research grant (H-3054) from the Heart Institute, National Institutes of Health. 'Serpasil', a brand of reserpine 2·5 mgm./ml., was generously presented by the Ciba Pharmaceutical Products, Inc.

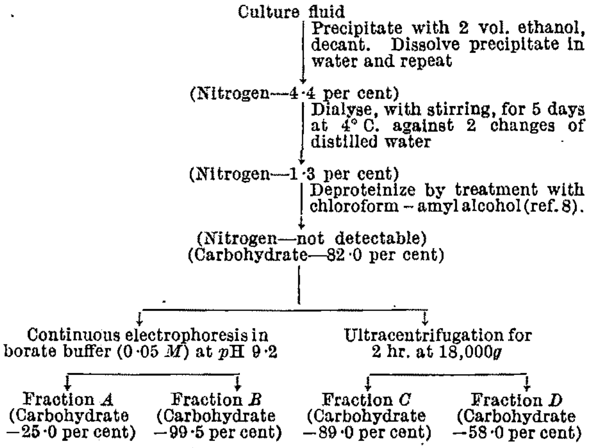
Extracellular Metabolic Products of a *Hirsutella* Species

A species of *Hirsutella*, parasitic on larvæ of the spruce budworm (*Choristoneura fumiferana* (Clem.))[1], when grown in liquid culture produces a highly viscous metabolite. Preliminary tests indicated that this substance might be a polysaccharide and since it has been reported that polysaccharides produced by some parasitic fungi can cause significant reactions in the host[2], it seemed desirable to investigate this material.

The fungus was grown in a liquid medium containing 1 per cent glucose and 1 per cent 'Difco' yeast extract. 100-ml. portions of the sterile medium in 250-ml. flasks were inoculated, incubated for 7–10 days at 25° C. on a rotary shaker, pooled, centrifuged, and the supernatant fluid collected.

The addition of two volumes of ethanol or acetone to one volume of the culture fluid precipitates the viscous material. Spot tests on this precipitate gave positive results for the presence of carbohydrates and proteins and/or amino-acids. Reducing sugars were detected only after acid hydrolysis of the sample. Negative results were obtained in tests for pentoses, galactose and glucuronates, while ether extraction of an acid hydrolysate of the sample gave no evidence for the presence of lipids.



Culture fluid
Precipitate with 2 vol. ethanol, decant. Dissolve precipitate in water and repeat
(Nitrogen—4·4 per cent)
Dialyse, with stirring, for 5 days at 4° C. against 2 changes of distilled water
(Nitrogen—1·3 per cent)
Deproteinize by treatment with chloroform – amyl alcohol (ref. 8).
(Nitrogen—not detectable)
(Carbohydrate—82·0 per cent)
Continuous electrophoresis in borate buffer (0·05 M) at pH 9·2
Ultracentrifugation for 2 hr. at 18,000g
Fraction A (Carbohydrate —25·0 per cent)
Fraction B (Carbohydrate —99·5 per cent)
Fraction C (Carbohydrate —89·0 per cent)
Fraction D (Carbohydrate —58·0 per cent)

The material was purified as in the scheme above. During the fractionation in the continuous electrophoresis apparatus fraction *A* was collected directly below the point of application. Fraction *B* migrated toward the anode but was carried down the paper at such a slow rate that it had not reached the bottom edge before the end of the run. However, as the streak was clearly visible it was cut from the paper, eluted with water, filtered through a sintered glass funnel to remove cellulose fibres, and freed of borate[3].

When the deproteinized culture fluid was centrifuged for 2 hr. at 180,000*g*, it yielded a semi-solid sediment and a non-viscous supernatant which could be siphoned off. The sediment (after washing 4–6 times with water) and the supernatant were freeze-dried and designated fractions *C* and *D* respectively.

The time-reaction curves of all four fractions with anthrone were, in general, similar to those reported by Koehler[4] for the polyhexoses glycogen, dextrin and amylose. The shape of these curves indicated that the samples contained aldohexoses only.

Hydrolysis of the samples by refluxing with 1 *N* sulphuric acid resulted in the formation of considerable amounts of humin and almost complete destruction of the sugars. However, by heating with 2 *N* formic acid in sealed tubes at 120° C. complete hydrolysis could be obtained with destruction of less than 5 per cent of the carbohydrates. Chromatograms of the hydrolysates of fractions *A* and *B* showed three spots, two of which were identified as glucose and mannose but the third was not identified. When hydrolysates of fractions *C* and *D* were subjected to chromatography only two spots, corresponding to glucose and mannose, were apparent. It appeared, therefore, that the third component in fractions *A* and *B* might be an artefact formed during the fractionation by electrophoresis, possibly due to the long exposure to alkali.

The sugars were also identified by filter paper electrophoresis of the hydrolysates[5]. Glucose was further confirmed by treating the hydrolysates with glucose oxidase. Chromatography of the treated samples showed that one spot, corresponding to the glucose standard, had disappeared.

The infra-red spectra of the fractions gave some additional information on the nature of these carbohydrates. A peak at 890 ± 10·5 cm.$^{-1}$ in all the samples can be attributed to a β-linkage in the polysaccharides. There was no evidence of a peak at

844 cm.$^{-1}$ in any fraction, which indicates that the α-linkage is not present to any extent in these samples[6]. All four fractions gave a peak (814 ± 9·5 cm.$^{-1}$) which appeared to be similar to a type 3 peak of mannan. Other peaks given by fractions *A* (917 cm.$^{-1}$) and *B* (947 ± 1·4 cm.$^{-1}$; 774 ± 1·2 cm.$^{-1}$) are typical of hexoses in general and could not be attributed to any particular sugar[7].

Sedimentation curves gave an indication of the homogeneity of the samples. The deproteinized, but unfractionated sample was heterogeneous but contained two principal components. Fraction *A* was heterogeneous with no predominant component but fraction *B* gave a single, sharp peak indicating that it was relatively homogeneous. Both fractions *C* and *D* were heterogeneous, but each contained one main component.

This fungus produces a number of extracellular polysaccharides, though there appear to be two main constituents in the mixture. While these polysaccharides are similar in some respects, for example, constituent sugars and β-linkages, there are differences in molecular weights and in viscosities. The one polysaccharide isolated in a relatively pure form differs from the others in that it can form a charged complex with borate. Since the formation of borate complexes depends on the location of free hydroxyl groups in the polymer, a difference in the position of the glycosidic linkage in the polymers may be indicated.

Purine Excretion by the Sheep Ked, *Melophagus ovinus* (L.)

THE major nitrogenous excretory product of adult insects is uric acid[1]. Small amounts of the enzymes adenase and guanase have been reported in *Hydrophilus* and *Dytiscus*[2] and in *Prodenia* and *Tenebrio*[3]. Larvæ and pupæ of *Antheraea pernyi* Guér. (Lepidoptera) contain adenine, hypoxanthine and xanthine[4]. At Lethbridge, female sheep keds have been found to excrete xanthine and hypoxanthine as well as uric acid. Male keds excreted only uric acid.

Purines were determined chromatographically by adapting the method of Vischer and Chargaff[5]. Direct squashes of the hæmolymph, Malpighian tubules, and iliac bulb contents of two or three insects were made on Whatman No. 4 filter paper, each squash being treated with 0·5 *N* sulphuric acid after spotting. About 0·05 ml. of a standard mixture (hypoxanthine, 0·1 per cent; xanthine and uric acid, saturated solutions) in 0·5 *N* sulphuric acid was spotted on the paper and run beside the squashes. Chromatograms were run by the descending technique for 16 hr. in a system composed of *n*-butanol/diethylene glycol/water (4 : 1 : 1), in an atmosphere saturated with this material and with ammonia. The latter neutralized the sulphuric acid used in spotting the standards and samples. Chromatograms were air-dried, oven-dried for 30 min. at 40° C., sprayed with a 0·5 *M* solution of mercuric nitrate in 0·5 *N* nitric acid, washed in 0·5 *N* nitric acid and running tap-water, and developed in ammonium sulphide solution. Purines appeared as black spots of mercuric sulphide.

Great variation was noted in the amounts of xanthine and hypoxanthine from random samples of female keds, and an attempt was made to discover the source. Chromatograms of hæmolymph, tubules, and iliac bulb contents of females containing no larva in the vagina showed only uric acid, whereas those containing a small larva exhibited traces of xanthine as well. Squashes from females containing a large larva produced xanthine spots as dense as or denser than the uric acid spots, as well as small spots of hypoxanthine, which was usually demonstrable only in the iliac bulb contents. It was concluded that the xanthine and hypoxanthine were produced in larval metabolism.

Formation of Antifungal Antibiotics by a New *Streptomyces* Species

Two closely similar strains of a new species of *Streptomyces* (Nos. 1033 and 1038) were isolated from the Champavathi river mud (Andhra Pradesh) and Bangalore virgin soil (Mysore State). Their morphological and biochemical characteristics (Table 1) appear similar to those of *Streptomyces viridans* (Waksman and Henrici's classification)[1], but they are readily differentiated from the latter by the formation of straight sporophores and aerial mycelium in circles and tufts, and the elaboration of antifungal substances.

A mixture of three antibiotics, *A*, *B* and *C*, extractable with *n*-butanol from broths and mycelia, is formed after growth for 48–72 hr. in shake-cultures containing molasses and peptone at 28° C. None of them has yet been obtained in the crystalline state. These are characterized by a high degree of inhibitory activity (0·2–0·5 μgm./ml.) *in vitro* against *Saccharomyces cereviseae*, *Candida albicans*, *C. tropicalis*, *Zygosaccharomyces priorianus*, *Torulopsis pulcherimma*, *T. utilis*, *Rhodotorula glutinis*, *Geotricum* sp. and a few other fungi tested. They are inactive towards *Micrococcus pyogenes* var. *aureus*, *Escherichia coli* and *Bacillus subtilis*. The mixture of the antibiotics separates into three spots (R_F values, 0·0; 0·33 and 0·95, respectively) on one-dimensional ascending paper chromatograms (Whatman No. 1 paper) developed with benzene/acetic acid/water (2 : 2 : 1 —organic layer) at 26° C. While *A* and *B* give

Table 1. Characteristics of the Organisms after Incubation for Seven Days at 28° C.

Media (ref. 2)	Description of colony	Reverse side	Aerial mycelium	Soluble pigment
Yeast-glucose agar	Good growth, round, raised; older colonies often cleave	Moss green	Light grey with greenish tinge, concentric, abundant velvety rings and tufts. Sporophores curved; spores globose	Greenish, darkening later
Nutrient salt agar	"	"	"	"
Glucose-peptone agar	"	"	"	Slight
Meat peptone agar	As above, but flattened; growth, poor	Yellowish green	"	None or faint

Toxicity of Urea to Sheep

It is generally accepted that urea is toxic when fed at levels greater than 30–35 gm. per sheep a day. Clark *et al.*[1] produced toxic effects by drenching sheep with 10 gm. of urea. Peirce *et al.*[2] killed many sheep when they fed 25–45 gm. of urea per sheep a day; in this experiment, the daily ration of urea was consumed over a period of approximately 1 hr. By adjusting the method of feeding, we have found it possible to feed sheep up to 100 gm. of urea a day with no mortality.

Although the mechanism of urea toxicity is not fully understood, it is thought to be related to the production of ammonia by the rapid hydrolysis of urea in the rumen. This rise of rumen ammonia produces a rise of peripheral blood ammonia, and toxicity occurs when blood ammonia concentration rises above 8–12 μgm. ammonia–nitrogen/ml. However the ammonia concentration in peripheral blood does not rise until the rumen ammonia-level is raised above about 80 mgm. ammonia–nitrogen/100 ml.

It follows, therefore, that if the urea can be fed in such a way that rumen ammonia-levels never rise above 80 mgm. ammonia–nitrogen/100 ml., then no toxicity will result. This can be done by spraying the urea in solution over the sheep's ration of hay, or over the pasture which it is grazing. In this way, the daily ration of urea will be consumed in small quantities at intervals over the whole 24-hr period. Since ammonia is rapidly absorbed from the rumen, there will be no great build up of rumen ammonia.

A Corriedale wether weighing 58·5 kgm., and fitted with a permanent rumen fistula, was kept in a metabolism cage and fed a daily basal ration of 1,400 gm. chopped meadow hay (crude protein 7·0 per cent). From day to day, this was supplemented with varying amounts of urea and molasses, these being incorporated into the ration as a solution in water mixed thoroughly with the hay. The urea : molasses ratio by weight was kept at 1 : 4. Rumen samples were taken immediately before feeding and then at regular intervals after feeding for periods up to 24 hr. Rumen *p*H and rumen ammonia concentration were measured on each sample.

Fig. 1 shows rumen ammonia concentrations over a 14-hr. period after feeding 100 gm. of urea, and, for comparison, the effect of introducing 25 gm. of urea directly into the rumen, and of feeding hay alone. When 100 gm. of urea were fed with the hay, rumen ammonia-levels rose sharply and remained at high levels throughout the day, the levels fluctuating slightly according to times of eating. However, at no time did these levels rise above 80 mgm. ammonia–nitrogen/100 ml. Similar results have been obtained

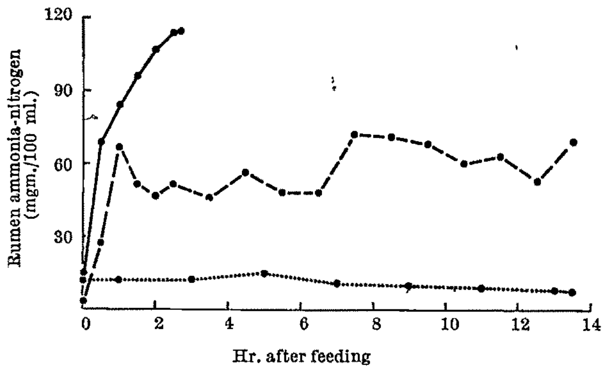

Fig. 1. The effect of different ways of feeding urea on rumen ammonia-levels: ● · · · ●, hay alone; ● – – ●, hay sprayed with 100 gm. urea + 400 gm. molasses; ● — ●, hay diet, 25 gm. urea through fistula

with other sheep both in metabolism cages and under field conditions.

Clearly, where urea is to be used as a supplement for grazing animals, it is desirable to feed it as a spray rather than as part of a concentrated ration, because toxicity is then no longer a problem. However, whether it is beneficial and economic to feed very high urea levels is doubtful.

It is interesting to note that when high levels of urea are fed, rumen *p*H rises to nearly 8, and both rumination and rumen movement are inhibited. Whether this rumen paralysis is caused by the ammonia *per se*, or is a consequence of rumen alkalosis, or is an osmotic effect, is not yet clear.

This work is continuing, and will be published in full elsewhere.

Heparin Content of Adipose Tissue

There is now a well-established association between heparin and clearing factor[1,2] and between heparin and the mast cell[3]. It has long been known by histologists that mast cells "are numerous in parts where fat is being laid down"[4]. This, and the extraction of active clearing factor preparations from adipose tissue[5], suggested to us that heparin might be an essential agent in fat mobilization and deposition, and in consequence be present in all animal fat. As a preliminary step we have determined the amount of heparin in the adipose tissue of cattle and the study forms the subject of this communication.

The tissues, already carefully trimmed, were kindly supplied by Mr. A. J. Ross of the Glasgow Abattoir and his description of them appears in Table 1.

Table 1. The Heparin Content of Bovine Adipose Tissue before and after Defatting

Type of fat	I.U./gm. whole adipose tissue	I.U./gm. of defatted adipose tissue residue
Intestine	0·92	21·6
Rectum and anus	1·5	60·0
Liver	1·3	45·3
Cardiac	1·0	40·3
Uterus	2·0	56·9
Lung	3·89	130·5
Kidney	0·44	28·7
Tongue	0·88	28·3
Mesentery	1·5	45·01
Stomach	0·9	59·0

Each sample of approximately two kilos was defatted with hot alcohol and the fibrous residue dried *in vacuo*. The heparin was then extracted as follows.

The defatted tissue was homogenized in 10 per cent aqueous ammonium carbonate, heated to 70° C. and filtered. The residue was twice re-extracted using further ammonium carbonate solution and the extracts were combined. The crude heparin was precipitated with two volumes of alcohol, collected by centrifuging and dried. The precipitate was taken up in ammoniacal water to give a gelatinous solution which was treated with trypsin and then assayed for heparin.

We are indebted to our colleague Mr. J. Pritchard for the anticoagulant assays[6], and on a random selection of samples he also demonstrated that the anticlotting activity was inhibited by protamine, indicating that the activity was due to heparin or similar substances.

Table 1 summarizes the results and shows that all samples contain heparin in appreciable amounts.

We are indebted to the Directors of Evans Medical Supplies for providing the facilities to carry out this work.

Difference between Lipoprotein Lipase and Post-Heparin Esterase in Human Serum

The basic component of the clearing factor[1] is a lipolytic enzyme which differs from hitherto known lipases[2]. Its lipolytic action can be demonstrated by the hydrolysis of the fatty components of lipoproteins[3]. When using β-naphthyl laurate[4], acetylcholine and butyrylcholine[5] as substrate the results are negative. With tributyrin the findings are conflicting[6]. If ethyl butyrate is used as substrate, raised esterolytic activity of the sera can be observed in man after the intravenous injection of heparin[7].

We consider that the acceleration of hydrolysis of ethyl butyrate is the result of the action of an enzyme other than the lipase of the clearing factor, which is definitely inhibited by protamine and heparin *in vitro*[8]. As against this, the post-heparin esterase splitting of ethyl butyrate is not inhibited by these substances (Table 1).

Table 1. The Resistance of Post-Heparin Esterase to Inhibition by Protamine and Heparin *in vitro*

Inhibitor of lipoprotein lipase	Amounts of inhibitor added per ml. serum	Esterase activity per ml. (μmol. of acid liberated from ethyl butyrate in 24 hr.) Pre-heparin serum	Post-heparin serum
Protamine	1,000γ	130	167
	100γ	131	166
	Control	130	167
Heparin	1,000 units	133	195
	100 units	135	198
	Control	135	195

In vitro, protamine inhibits post-heparin esterase only when it is added in excess[9]. Ordinary amounts, which inhibit the lipase of the clearing factor, have no effect, however, on post-heparin esterase. In accord with the findings of Levy and Swank[10], we found that protamine has an inhibitory effect on the activity of post-heparin esterase *in vivo*[11]. It may therefore be concluded that heparin produces an increase of esterase in the blood-stream, but that it does not form a component part of the molecule of this enzyme. As opposed to this, lipoprotein lipase contains heparin or a similar substance, which explains its inhibition by protamine *in vitro* and its destruction by heparinase[12].

Interaction of Gibberellic Acid and Photoperiod on the Vegetative Growth of *Pinus elliottii*

CONIFERS have not been very responsive to treatment with gibberellic acid. A definite stimulation of extension growth was obtained by Marth *et al.*[1] in only two of the five species investigated, *Pinus virginiana* Mill., and *Juniperus chinensis* f. *Pfitzeriana* Spaeth. Measurable, but not significant, increases in height growth of treated *Pinus strobus* L. have been reported[2]. Radicles of germinating seeds of *Pseudotsuga menziesii* (Mirb.) Franco elongated more rapidly if wetted with weak solutions of gibberellic acid[3].

The effect of this chemical on stem growth has generally been tested under natural photoperiod or under long days. The results presented here indicate that gibberellic acid promotes the growth of slash pine, *Pinus elliottii* Engelm., only under short-day conditions.

Shortly after emergence in February 1957, the pine seedlings were submitted to one of the following photoperiods: 8, 16 and 24 hr.; and natural day-length. The supplementary light was provided by incandescent bulbs giving an intensity of about 20 foot-candles at the level of the plant tips. Shoot elongation increased with increasing photoperiod. After four months, the average height of the seedlings under short days (8 hr.) was equal to 44 per cent of those in continuous light, whereas the 16-hr.-day plants were 70 per cent as high. Even in continuous light, slash pine elongates by flushes of growth, once it has formed secondary needles. The short-day seedlings produced only two flushes separated by a long time-interval. Practically no growth in height occurred in these seedlings between June and December. Starting then, half of them were sprayed, once every 14 days, with a 0·1 per cent aqueous solution of 'Gibrel' (potassium gibberellate) to which a few drops of a wetting agent had been added. Prior to spraying, the plants were slightly wounded by breaking off several primary needles to facilitate penetration of the chemical. The controls were subjected to the same mechanical injury.

Fifteen days after the first application, the terminal buds of several seedlings were swollen and had elongated slightly. One week later, 14 out of 25 treated plants had broken dormancy, and, one month after the initiation of the treatments, they were all actively growing. Most control plants began to break dormancy shortly after the treated plants but their height-growth lagged and stopped earlier. By May 15, the treated seedlings had grown an average of 67 mm. (52 per cent of initial height), significantly more than the controls (30 mm., or 24 per cent of initial height).

Gibberellic acid was also applied, as a spray and in a 1 per cent lanolin paste, to seedlings growing under natural and 16-hr. photoperiods and in continuous light. There was a small, but not significant, increase in average height-growth in natural day-length (11–12 hr. at that time), but no response was observed under long days.

In another experiment, four-month-old seedlings, that had been growing actively under 16-hr. days, were submitted to 8-hr. days in order to induce dormancy. This condition was obtained in 2–4 weeks. Gibberellic acid sprays were then administered at weekly intervals. The first signs of growth resumption appeared one month after the first treatment. Three months later, the forty treated plants had elongated by 26 mm. on the average, or 16 per cent of initial height, whereas the controls produced new needle fascicles but very little shoot-growth (8 mm. on the average, or 5 per cent of initial height). Seedlings of the same age submitted to long days showed no detectable response to the chemical.

It seems that, in slash pine, gibberellic acid is able to break the type of bud dormancy induced by short-day treatment, and to stimulate the growth of elongating shoots exposed to short photoperiods. The lack of response to the chemical in the long-day treatments suggests that the natural gibberellin factor becomes deficient, in this species, only under short days. In contrast to slash pine, two other conifers, *Pinus coulteri* D. Don and *Pseudotsuga macrocarpa* (Vasey) Mayr, did not respond to gibberellic acid under short days (while *Camellia japonica* L., an evergreen angiosperm, reacted positively)[4].

Interactions between gibberellic acid and photoperiod have also appeared in a preliminary study on bud-break in deciduous species. In some of these (for example, *Acer platanoides* L.), the chemical hastened bud opening to a greater extent under short days than under long days.

Acknowledgments are due to Dr. Richard M. Klein for advice. The 'Gibrel' was presented by Merck and Co., Inc.

Cocoa Shade and Manurial Experiment in Ghana

Contrary to general experience with other world crops, cocoa grown in West Africa had never been shown to respond to fertilizer, for reasons discussed by T. N. Hoblyn[1]. The recent successful control of capsid pests and the availability of uniform cocoa, however, has now made accurate experimentation possible.

In October 1956, at this Institute an area containing ten-year-old Amelonado trees planted in straight lines at 8 ft. × 8 ft. under uniform *Gliricidia maculata* shade (24 ft. × 24 ft.) was chosen for shade removal and fertilizer application. The trees were in their third year of bearing and pre-treatment records were available. Fifteen plots, each containing 300 trees, were marked out. The treatments applied were: original shade/no fertilizer; original shade/fertilizer mixture; no shade/no fertilizer; no shade/fertilizer mixture. All treatments are replicated three times, each replicate having 300 trees, thus making a total of 3,600 experimental trees. The three extra plots form guard plots between shaded and unshaded cocoa.

The fertilizers were broadcast by hand, and the types, rates and times of application are shown in Table 1.

Table 1

Application	Date	Fertilizer used in mixture	Rates (lb./acre) N	P_2O_5	K_2O	MgO
1	Oct. 1956	Ammonium phosphate (11 per cent N, 46 per cent P_2O_5) Single superphosphate (18 per cent P_2O_5) Sulphate of potash (48 per cent K_2O) Magnesium sulphate (16·2 per cent MgO)	13	91	90	46
2	April 1957	Urea (46 per cent N) Triple superphosphate (47 per cent P_2O_5)	50	30	—	—
3	Sept. 1957	Urea	50	—	—	—

The shade was removed from all the non-shaded plots by poisoning the shade trees with 'Phortox' in March–April 1957.

The yields, expressed in pounds dry cocoa per acre, after one year of treatment are given in Table 2.

Table 2. Yields expressed in lb. Dry Cocoa/Acre

Treatments	First fertilizer mixture applied October 1956. Shade removed March 1957. Pretreatment yields 1954–55	1955–56	1956–57	After treatment yields 1957–58
Original shade/no fertilizer	30	44	205	615
Original shade/fertilizer mixture	24	32	211	869
No shade/no fertilizer	19	29	170	1,079
No shade/fertilizer mixture	20	18	173	1,574

Shaded/fertilized, unshaded/fertilized and unshaded/unfertilized treatments all showed significant increases in yield compared with the shaded/unfertilized control when an analysis of covariance was carried out. It is realized that one year's results are not sufficient to provide any definite general conclusions; but the sparsity of published information about the responses of cocoa to such treatments, especially in West Africa, has caused us to report these preliminary results. Fuller details of the investigations will be published elsewhere.

Inheritance of Photoperiodic Reaction in Rice

Aus (summer) and *Aman* (winter) are the two important types of rice cultivated in Bengal, north-east India. The majority of the varieties of summer rice are photo-indifferent (period bound), while all the winter varieties are short-day (season bound) plants[1,2].

In practice, both summer and winter varieties are sown at the same time, at the beginning of the rice season in May–June, when the advent of rains ensures plenty of moisture required for good growth of the crop. The summer varieties, which are photo-indifferent, flower about 90 days after sowing and are ready for harvest in another month, in September. The winter varieties, which are short-day plants, do not flower until the length of the day decreases to less than 11·5 hr., in October–November. These varieties are harvested in November–December. As a rule, however, the winter varieties are much heavier yielders and better in grain quality than the summer varieties. It is of interest, therefore, to elucidate the inheritance of photoperiodic reactions in summer and winter rice, with the view of combining the early harvesting of the summer varieties with the high yield and good grain qualities of the winter varieties.

Reciprocal crosses were therefore attempted during the season of 1956 with plants, grown in pots, of two summer varieties, namely *Charnock* and *Dhairal*, and two winter varieties, namely, *Patnai*–23 and *Bhasamanik*, there being in all eight different combinations of crossings.

The combinations employed, the number of crosses actually attempted, the numbers of seeds gathered and of seeds germinating in the following season, and the number of plants showing hybrid characters under the respective combinations are shown in Table 1.

For these crosses flowering coincidence was effected in two ways. First, flowering of the winter varieties was hastened by short-day treatment to coincide with flowering of the summer varieties in their normal season. Secondly, a series of sowings of the summer varieties was made at fortnightly intervals until the end of August, to obtain coincidence of their flowering

Table 1

♀ Parent		♂ Parent	No. of flowers cross-pollinated	No. of seeds produced	No. of seeds germinated	No. of plants showing hybrid (F_1) characters
(1) *Bhasamanik*	×	*Dhairal*	44	15	14	1*
(2) *Dhairal*	×	*Bhasamanik*	37	8	5	1

(8) *Charnock* ♀ × *Patnai*-23 ♂	136·0	135·0	10·0	6·95	300
(9) *Charnock* ♀ × *Patnai*-23 ♂	137·0	138·0	11·0	8·9	350
(10) *Bhasamanik* ♀ × *Charnock* ♂	142·0	119·0	19·0	10·7	600

with that of the winter varieties in the normal season of the latter. The 'paper-bag' method was employed for opening flowers for emasculation[3].

In the season of 1957 the hybrid seeds were grown in pots to study their behaviour. Information on tillering, height, leaf size, flowering time and yield per plant was collected. Hybrid plants have been obtained from six of the eight combinations of crosses. Growth, flowering-time and yield of the hybrid plants, together with those of plants belonging to the parent varieties sown at the same time in 1957, are shown in Table 2.

The F_1 plants with all combinations of crosses show an intermediate effect on photo-periodic reaction, their flowering time being intermediate. The reciprocal crosses were identical.

In respect of growth characters, such as height, tiller number and yield, the F_1-hybrid plants of all six different combinations of crosses display hybrid vigour.

Further work is in progress.

A New Species of *Azotobacter* producing Heavy Slime and Acid

In the course of an investigation on the geographical distribution of the Azotobacteriaceae[1] in various types of soil in India, a nitrogen-fixing organism has been isolated from a sample of red soil from Pattambi (Madras) by Winogradsky's silica-gel plate technique and purified by dilution platings. This new bacterium differs in certain morphological and physiological characteristics from known species of *Azotobacter* (including *Beijerinckia*)[1]. The cells are oval in shape, occur mostly in pairs and packets and sometimes singly, measuring on an average 1·2–2·2μ × 2·3–4·6μ (Fig. 1). The cells do not change their shape even on prolonged incubation in Ashby's nitrogen-free liquid medium with different carbohydrates. The bacterium encysts after 30 days incubation at 30° C. in the solid mannitol medium without calcium carbonate. The optimum temperature for growth was found to be about 30° C.

The colonies are usually raised, oval or circular and sometimes elongated with an average diameter of 2·95 mm. × 1·55 mm. on Ashby's nitrogen-deficient agar medium after 10 days incubation at 30° C. Colonies are transparent at first and gradually become opaque and sometimes curled if the medium is devoid of calcium carbonate. In streak cultures, the organism forms a slimy growth of variable thickness. In Ashby's nitrogen-free glucose or sucrose medium without calcium carbonate, the slimy masses at first accumulate on the surface of the medium, which is entirely transformed to a jelly-like consistency in about one month. Slime production is always associated with the growth of the organism. With calcium carbonate present in the medium, however, growth is depressed to some extent.

The organism is aerobic, non-motile, and the cells are Gram-negative. It produces no colour even on addition of a small amount (10γ per litre) of copper sulphate in Ashby's nitrogen-deficient agar medium[2], but some rust-brown sediment occasionally occurs in the nitrogen-free solid medium after six weeks incubation at 30° C. This sediment does not dissolve in alcohol, ether or chloroform.

The bacterium is usually resistant to certain basic aniline dyes, namely, crystal violet, gentian violet, safranine and methylene blue. However, staining is accomplished when the dyes are mordanted with phenol or aniline. The cells are stained by both basic carbol-fuchsin and aniline gentian violet on slight warming.

This bacterium produces acid from all the carbohydrates in nitrogen-free medium, especially glucose, sucrose, mannitol, starch, galactose, raffinose, mannose, maltose and dextrin. The development of acidity is the quickest in glucose, and is delayed

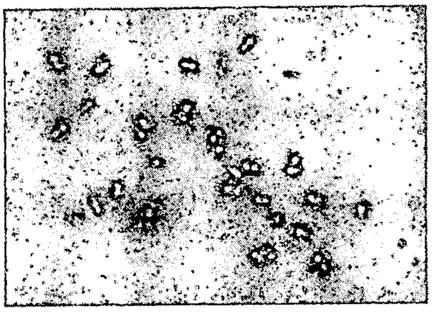

Fig. 1. *Azotobacter acidum*: a new species of *Azotobacter* producing heavy slime and acid. (× 500)

much in mannitol. Growth ceases when the *p*H of the medium falls below 4·0.

The organism fails to grow in organic sources of nitrogen, but with inorganic nitrogen (both with NH_4^+ and NO_3^-) the growth is accelerated with a rapid fall of *p*H and it ceases to grow after 10 days at 32° C. The bacterium does not grow either in nutrient broth or in peptone agar containing 0·5 per cent glucose. No gas is evolved during break-down of carbohydrates. In potato slants, cream-coloured growth appears in 4 days at 30° C. The organism can hydrolyse starch, and good amylase activity is observed after 6 days incubation at 30–32° C. It does not liquefy gelatine and produces no change in litmus milk during a period of 3 weeks at 30–32° C. The bacterium does not form indol or acetyl-methyl carbinol. It neither reduces nitrate nor produces ammonia.

The bacterium fixes on an average 8–10 mgm. of nitrogen per gram of glucose or sucrose added in Ashby's nitrogen-free solution without calcium carbonate after 3 weeks incubation at 32° C.

The organism differs from *Az. chroococcum* and *Az. beijerinckii* in that it forms acid from different carbohydrates and withstands acidity up to *p*H 4. Moreover, it produces no colour even on addition of copper sulphate. The cells are smaller and do not form streptococcus-like chains. The bacterium differs from *Az. agile* and *Az. vinelandii* in that it lacks motility ; it fails to grow in nutrient broth even with glucose and it does not form any fluorescent green pigment. Unlike *Az. indicum*, the cells lack fats and form cysts in the solid nitrogen-free carbohydrate medium. In Ashby's nitrogen-free medium with dextrin, *Az. indicum* fails to grow, while the new organism shows good growth. *Az. indicum* produces turbidity in the liquid medium with the formation of some sediment, but the new organism gradually changes the consistency of the medium to a semi-solid.

The differences between the morphological and cultural characters of the bacterium described here and other known species of *Azotobacter*[3] indicate that the organism is a new species. It is proposed that it should be named *Azotobacter acidum*, due to its property of forming acids from carbohydrates. Details of this work will be published elsewhere.

A New Type of Early Cysticercoid Stage in a Cyclophyllidean Cestode

Cysticercoids of various cyclophyllidean families are known to occur in small invertebrate hosts, commonly in arthropods and very occasionally in molluscs and annelids. During the course of some work on the pulmonate snail, *Oxychilus cellarius* (Müll) one of us noted a 3 per cent infection of the peritoneum around the digestive gland and gut with cysticercoids of what we believe to be a member of the Dilepididae, the first such record from a mollusc. The cysts numbered from one to about fifty in a single specimen and were seen in various stages of development, ranging from what we consider to be the pre-cystic stage to the fully formed, infective cysticercoid. The older cysticercoids with completely formed scolex and bladder resemble very closely the corresponding stage of another cysticercoid of the Dilepididae—that of *Choanotaenia infundibulum* (Bloch) described by Reid and Ackert[1]. A full account of these stages will be published later, but meanwhile we wish to direct attention to the earliest stage of this cysticercoid—a form which we regard as being pre-cystic and which, so far as we are aware, is unlike anything previously described.

From some of the younger cysts, the walls of which are adventitious host structures formed from peritoneum surrounding the parasite, tailed larvæ (Fig. 1) were extracted which were quite actively mobile in saline, bearing a marked resemblance in their movements to digenetic cercariae. We think that such a form must have been only very recently encysted, having reached its position by movement of the tail. Mobile, tailed larvæ of this kind have been reported only twice before in the Cestoda, in each case in the life-cycle of *Dipylidium caninum* L. by Grassi and

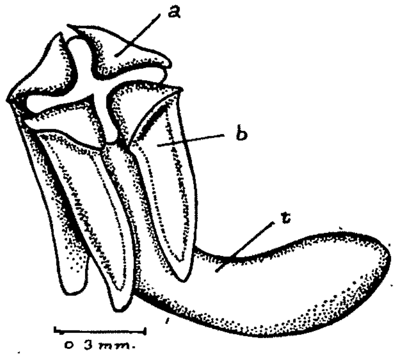

Fig. 1. Pre-cystic stage drawn from living specimen. For key see Fig. 2

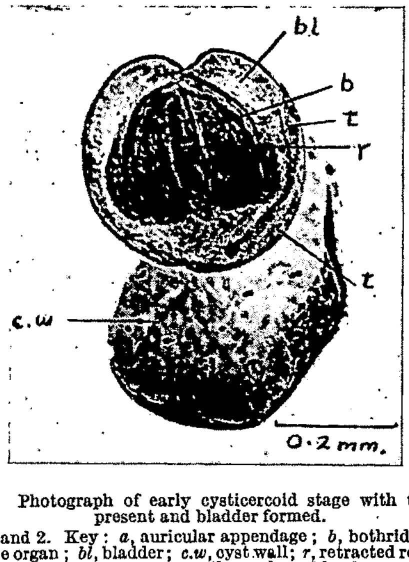

Fig. 2. Photograph of early cysticercoid stage with tail still present and bladder formed.

Figs. 1 and 2. Key : *a*, auricular appendage ; *b*, bothridium-like adhesive organ ; *bl*, bladder ; *c.w*, cyst wall ; *r*, retracted rostellum with double coronet of rose-thorn-shaped hooks ; *t*, tail

Rovelli[2] and Vennard[3]. The former writers compared its movements with those of cercaria, and Janicki[4] quotes this as part of the evidence for his 'Cercomer theory' in which he attempts to explain a possible derivation of the cestodes from the Digenea.

The tailed larva in the present work differs from any other tailed cysticercoid now known, either encysted or free, in possessing, instead of typical acetabula, four elongated muscular adhesive organs which resemble the bothridia of the Tetraphyllidea. It is not possible at present to say whether these structures are true bothridia or whether they are clearly demarcated at this stage from the rest of the scolex musculature, but they rapidly become acetabular by definition while still bothridia-like in shape, in the developing cysticercoid (Fig. 2). In the earlier stage (Fig. 1) each bothridium-like structure bears anteriorly an auricular appendage similar to those in the plerocercoid and adult of the tetraphyllidean *Dinobothrium plicitum* Lint. and also those of adult Tetrabothrioidea. As the cysticercoid approaches the infective stage, however, the whole muscular organ (bothridium-like structure plus its auricular appendage) resolves itself to form an acetabulum like that of typical Cyclophyllidea.

Whether or not this larva establishes affinity with the Digenea or Cestodaria or both must still be a matter of opinion; it is possible that similar tailed pre-cystic stages exist in other cyclophyllidean life-histories where encysted tailed cysticercoids have been described, for example, *Choanotaenia infundibulum* and various species of *Hymenolepis*. In these, as in *Dipylidium caninum*, the tailed condition would relate to the fluid medium supplied by the arthropod hæmocœle. It is possible that in the mollusc, which is most frequently the host for the cercaria stage of the Digenea, conditions encourage this possible larval adaptation to persist for a longer period. Whichever way the characteristic cercaria tail is interpreted, there can be little doubt that the presence of a tetraphyllidean type of adhesive organ on the scolex, occurring at a stage shown to be much telescoped in other cestode life-histories, must be further evidence of the tetraphyllidean origin of the Cyclophyllidea.

Spawning Catfish with Mammalian Hormones

WE have already reported[1] that the catfish (*Heteropneustes*, *Clarias*) available locally respond to large doses of mammalian chorionic gonadotrophins ('Physex': Dumex; 'Antuitrin *S*': Parke, Davis), yielding viable eggs hatching into fry. Having tried the other mammalian hormones available, we wish to record the reactions of catfish not only to them but also to the same hormones used in combination with a threshold dose (*vide infra*) of catfish pituitary gland. In discussing the action of mammalian hormones, Hoar[2] stated that ". . . fish are so unresponsive to many mammalian (and bird) preparations that it is generally impractical to use them. The fish culturist or physiologist who wishes to hasten gonad development in fish is advised to use fish pituitaries". However, Kirshenblat[3] secured viable eggs of *Misgurnus* using methyl testosterone, progesterone and deoxycorticosterone acetate.

Heteropneustes (*Saccobranchus*) usually breeds during July–September, the monsoon months in South India. During February and March, growing ova are noticed in them and the ovary is in stage 4 according to the international maturity scale. We have found that a homoplastic parenteral injection of a dose equal to one-eighth of a gravid pituitary gland does not affect the ovary greatly; the catfish do not spawn and on stripping they yield few ripe eggs. This, therefore, may be taken as a dose to prime the ovary and used as the threshold dose to study the synergic action of the mammalian hormones injected into catfish. A homoplastic injection of a quarter gland of *Heteropneustes* pituitary makes them yield a large number of ripe eggs.

Mammalian follicle-stimulating and luteinizing hormones (Armour Laboratories, Chicago) have caused *Heteropneustes* to spawn and yield a large number of viable eggs[4]. The response of the fish to the follicle-stimulating hormone is obviously due to the small amount of luteinizing hormone present in it; this was afterwards confirmed by Dr. I. Bunding (Armour Laboratories, Chicago). He also stated (*in lit.*) that American minnows could not be made to spawn with similar mammalian gonadotrophic hormones sent to us. Hasler and Meyer[5] also failed to cause goldfish to spawn with purified mammalian luteinizing hormone; the fish also proved refractory, at certain dosage levels, to some mammalian pituitary suspensions[6]. Pregnant mare serum ('Antex': Dumex), œstrogen and progesterone have failed to make catfish spawn[1] and we have now found that methyl testosterone (Boots; 'Perandren' linguets: Ciba), deoxycorticosterone acetate ('Corlin': Glaxo), adrenocorticotropic hormone ('Adrenomone': Armour), growth hormone ('Somar': Armour) and oxytocin (Parke, Davis) are also ineffective in ripening the eggs of *Heteropneustes*. Kawamoto[7] tried unsuccessfully to obtain viable eggs from *Ctenopharyngodon* using sex hormones. On the other hand, catfish receiving a 2·5-mgm. dose of thyroid-stimulating hormone (Armour Laboratories) yielded viable eggs on stripping. This is probably the first instance where the thyroid-stimulating hormone has been used successfully for ripening fish ova. Pickford[8] indicated that thyroid activity may be necessary for gonad maturation, but there is no reference, so far as we are aware, to the use of thyroid-stimulating hormone as an ovulating agent.

We have therefore tried the other mammalian hormones in combination with a threshold dose of *Heteropneustes* pituitary gland. When gravid catfish are injected with a threshold dose equal to one-eighth of a pituitary gland combined with growth hormone, œstradiol dipropionate ('Ovocyclin *P*': Ciba), progesterone ('Proluton': Schering) and methyl testosterone respectively, the test animals gave many ripe and a large number of over-ripe eggs when stripped. Test animals receiving pregnant mare serum (75 I.U.), adrenocorticotropic hormone (10 U.S.P. units) and oxytocin (5 I.U.) respectively in combination with the threshold dose did not yield ripe eggs.

Two important points emerge from our bioassays. First, thyroid-stimulating hormone has been found to be an ovulating agent. Secondly, growth hormone, œstrogen, androgen and progesterone act as synergic agents when used along with a threshold dose of catfish pituitary gland, whereas pregnant mare serum, adrenocorticotropic hormone and oxytocin are ineffective.

Details of these experiments will be published in the *Journal of Scientific and Industrial Research*, New Delhi.

We wish to thank Prof. B. R. Seshachar for encouragement; Dr. I. Bunding (Armour Laboratories, Chicago) and Ciba Pharma Private Ltd., Bombay, for generous help with mammalian hormones and one of us (A. B. L.) is indebted to the Council of Scientific and Industrial Research, New Delhi, for the award of a scholarship.

A Lungfish (*Protopterus*) from the Middle Zambezi

THE Joint Fisheries Research Organization has been so fortunate as to acquire a lungfish from the Middle Zambezi. The specimen came, on May 15, 1957, from a stagnant 'backwater' of the Zambezi, at that time receding from its peak flood, in the Chipepo district on the northern bank, and was collected by Mr. Thayer E. Scudder, an anthropologist, who was at the time studying the local Gwembe Tonga people. Notwithstanding the fact that several fish-collecting expeditions have been made to this area, which is due shortly to be flooded by the waters of the Kariba dam, no other specimens are known from this region. However, it is known to the natives, who call it 'Ikana'. The fish is a specimen of *Protopterus annectens* (Owen), typically light-coloured ventrally, with the belly and lower head covered with conspicuous dark spots, and is of considerable interest in many respects.

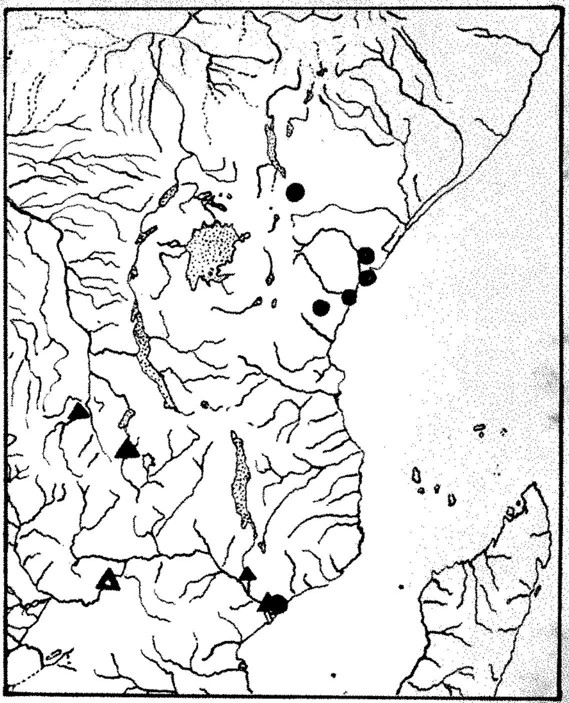

Fig. 1. Sketch map illustrating recorded occurrence of *Protopterus annectens* (▲), and *P. amphibius* (●), in East Africa and the Zambezi and Congo Basins. The locality of the new record is indicated by an open triangle (after Trewavas, ref. 1)

This is the first record of a lungfish from the Middle Zambezi system, which is faunistically divided from the Upper Zambezi by the Victoria Falls and the Lower Zambezi by the Kebrabassa rapids, so that each section of this great river has a characteristic fish-fauna. The Middle Zambezi may in general be regarded as intermediate in that, while it has itself few distinct species, the characteristic fishes of the Upper Zambezi, such as *Hemichromis fasciatus*, *Sarcodaces odoë*, *Tilapia macrochir*, etc., derived presumably from the Congo, and those occurring in the Lower Zambezi such as certain chondrichthyans, gobiids, ambassids, syngnathids, etc., which are derived from marine or estuarine faunas, are alike absent from it. Lungfishes have still not [illegible] been recorded from the Upper Zambezi, though enough circumstantial evidence exists to make their occurrence there probable.

Secondly, the locality of this specimen is intermediate between known records for *P. annectens* from the Lower Zambezi and the Lower Shire on one hand, and Katanga and the Lower Luapula on the other[1]. The present record is marked on the map of Fig. 1 as an open triangle.

A radiograph of the specimen revealed a third point of interest, namely, that it has only 32 pairs of ribs. According to Trewavas's recent study[1], it resembles in this respect a specimen from the Lower Shire (33 pairs) and Katanga specimens (32–33 pairs), while West African specimens have 34–37 pairs. Trewavas reasserts the specific distinctness of *Protopterus amphibius* (Peters), based on studies of material from Kenya darker, more thickset and with fewer ribs (27–29 pairs) than *P. annectens*. While the specific distinctness of this material is not to be doubted, the specific name *amphibius* was originally proposed by Peters[2] (*Rhinocryptis amphibia*) for specimens collected from Quelimane. Most of these have since proved to be *P. annectens*, and while one cannot as yet be certain on this point, it seems at present difficult to believe that there are two species of *Protopterus* in the Zambezi delta as maintained by Schneider[3]. There the species is based on one specimen stated to have 30 pairs of ribs, a number greater than that found in the Kenya specimens, and

Table 1

Total length (mm.)	278	Pelvic fin length (mm.)	76
Snout-vent length (mm.)	145	Pectoral fin-membrane width (mm.)	1·5
Snout-dorsal fin length (mm.)	77	No. of external gills	3

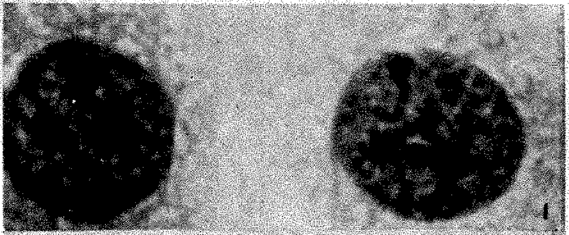
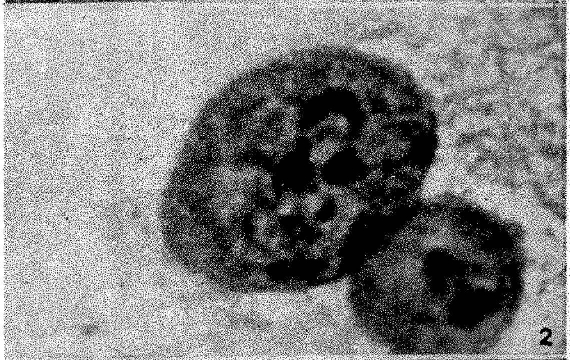
Representation of the X Chromosome in Intermitotic Nuclei in Man

IT is generally supposed[1] that there is a close relationship between the sex chromosomes and the nucleoli in most species, though the evidence for this in mammals is scanty[2]. It is nearly certain that the sex chromatin body[3] found in most nuclei in females of some species, including man, represents the heterochromatin of the *X* chromosome pair[4]. The demonstration of a persistent connexion between these bodies in some nuclei may serve to support both hypotheses. Reitalu[5] has described such a connexion in human fœtal liver; the matter seems important enough to justify this further description, based on observations, made in ignorance of Reitalu's, of similar structures seen elsewhere.

Thyroid tissue cultures offer exceptionally favourable material for the study of nuclear detail. We have used the primary outgrowths from fragments of human thyroid removed at operation, attaching the fragments to coverslips with plasma clot. In such preparations mitoses are rare, and most of the cells seen appear to be epithelial migrants from the original explant. Sex chromatin may be seen in as many as 90 per cent of nuclei. The nucleolar chromocentres are large and variable in number as well as size, though two is the commonest number. A well-defined strand of chromatin joining the sex chromatin to these chromocentres (Figs. 1, 2) is seen in perhaps 1 per cent of the cells. It is usually sinuous in its course and may bear one or two small chromatin granules; we have not been able to satisfy ourselves that it is clearly double in the manner of Reitalu's drawings. It is demonstrable only with difficulty in other material, but Fig. 3 shows a very clear example in a decidual cell from an abortion. Klinger's[6] illustrations (especially his Fig. 7) suggest that similar threads might be demonstrated in human amnion or chorion.

Reitalu describes this strand as a euchromatin thread joining two heterochromatin bodies. The heterochromatin of the sex chromatin must lie in the unpaired segment of the *X* chromosomes. We have failed to demonstrate any sex difference in the nucleolar chromocentres in several tissues, and conclude that they probably represent heterochromatin of the paired segment. These three linked structures must therefore represent a substantial part of the *X* chromosome, visible in the resting nucleus.





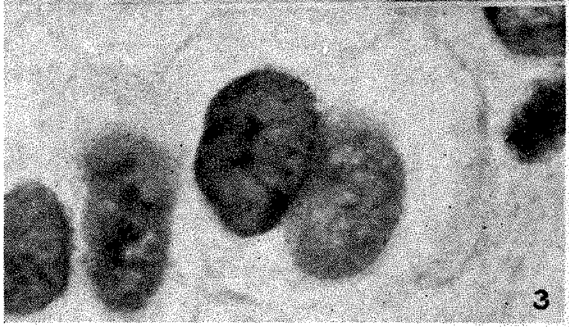


Fig. 1. Two nuclei from a thyroid tissue culture (female). On the left, the euchromatin thread is seen as a thick relatively ill-defined strand running down and to the right from the sex chromatin (at 12 o'clock) to join the right hand of the two nucleolar chromocentres. On the right, the euchromatin thread is very well defined, though its last part is out of focus: it runs from the sex chromatin (at 12 o'clock) to the left hand of the three nucleolar chromocentres. (Cresyl echt violet, × 2,000)

Fig. 2. An unusually fine and well-defined euchromatin thread, running from the sex chromatin (at 3 o'clock) straight to the nearest of the three nucleolar chromocentres. (Feulgen, × 2,000)

Fig. 3. Decidua from an abortion. A well-defined euchromatin thread running from the sex chromatin (at 4 o'clock on the nucleus of the central cell) to the nearest chromocentre. (Feulgen, × 2,000)

Evapo-transpiration from Different Crops exposed to the Same Weather

PENMAN[1] has concluded from a physical analysis of the process of evaporation that the rate of evapo-transpiration is the same for different crops exposed to the same weather provided that each crop covers the ground completely and is approximately of the same colour. Rider[2], however, has concluded from microclimatic measurements made above extensive areas of different crops that these can so modify the effective weather that large differences in the water loss from different crops can occur.

Table 1. ENERGY BALANCE, WELLESBOURNE (JUNE 6–OCTOBER 1, 1957)
Energy expressed as in. of water (1 in. = 1,500 gm.cal.)

Measurement	Method	Grass Daily irrigation	Grass Rain only	Carrots Daily irrigation	Carrots Rain only	Open water surface

Heat transfer: from air to crop	Calculated by subtraction	1·34	—	4·56	—	—
,, from crop to air		—	1·86	—	0·90	3·51

The evapo-transpiration from grass and carrots was measured at the crop weather station, Wellesbourne[3], continuously from mid-June until early October 1957 in the centre of plots 600 square yards in area. There were two soil-moisture treatments; in one the plants were irrigated each day to restore the soil to field capacity and in the other the plots received only rainfall. Each measurement was based on the mean of the readings from three similar lysimeters. The lysimeters used to measure evapo-transpiration in the plots supplied by rainfall only consisted of weighable monolith soil cores, whereas for the plots irrigated daily, drainage lysimeters[4] were used. The twelve lysimeters were buried to their rims and completely surrounded by plants which received the same soil-moisture treatment and were similar in size to those growing in the lysimeters. The instruments were tested before and after use and found to be water-tight.

Fig. 1 shows the measured cumulative evapo-transpiration from the grass and carrot crops plotted against the measured cumulative evaporation from a standard evaporation tank. The relation was linear in each case. The use of the evaporation tank readings as an index of the evaporative conditions is supported by the close agreement between the measured evaporation and that estimated by Penman's method[1].

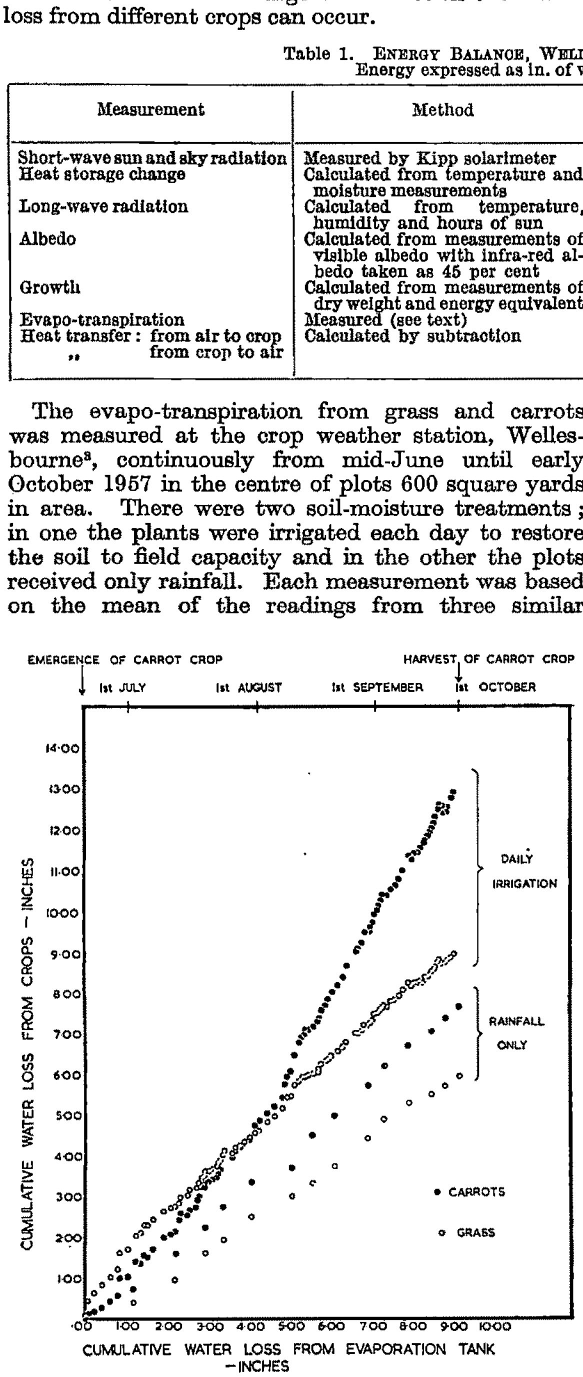

Fig. 1. Effect of crop type and soil moisture treatment on relative rate of evapo-transpiration

After the irrigated carrots had covered 40 per cent of the ground surface there was an alteration in the slope of the linear relation between evapo-transpiration from the crop and evaporation from the water tank (top line, Fig. 1), and further increases in crop cover and height had no effect on the rate of evapo-transpiration. With both grass and carrots receiving only rainfall the rate of evapo-transpiration was reduced by 40 per cent as compared with those that were irrigated.

Meteorological observations enabled the energy balance to be calculated for the grass and carrot crops grown under the two soil-moisture treatments and for the open water surface of the evaporation tank.

The differences in the amount of evapo-transpiration from the two crops could not be explained by the differences in the amount of energy used for growth, heat storage or for reflexion, so that large differences must have occurred in the amount of heat transferred to and from the air.

Similar comparisons are now being made with other vegetable crops in order that the relation between evapo-transpiration and evaporation from an open water surface may be established for crops usually irrigated.

Grateful acknowledgment is made to Miss J. I. E. Rubio for taking most of the measurements.

A Genetic Test for Side-chains in a Phage Chromosome

A NUMBER of authors[1] have proposed side-chain models of the chromosome. The chromosome, as suggested most recently by Taylor, consists of a double core or central backbone, with double deoxyribonucleic acid helices[2] attached at right angles. These double helices are connected to the core at specific attachment points so that one polynucleotide chain of each helix is attached to one half of the core and the other polynucleotide chain to the other half.

This side-chain model is of interest for a number of reasons. (1) Its double structure is compatible with the organization and duplication of chromosomes as revealed by the studies of Taylor, Woods and Hughes[3] using tritium-labelled thymidine. (2) Despite the calculations of Levinthal and Crane[4] suggesting the feasibility of unwinding long double deoxyribonucleic acid helices, unwinding and separation of relatively short deoxyribonucleic acid helices arranged as side-chains is more easily visualized. (3) Conventional crossing-over would take place along the central backbone, and additional recombinations could occur on the side-chains. (4) Negative interference and gene conversion can be explained in at least a formal manner by side-chains.

We have found no evidence for side-chains using a genetic test on bacteriophage *P*22 of *Salmonella typhimurium*. The test could detect the occurrence of two loci on the same side-chain. The only requirement of the test is the presence of marker loci to either side of the two loci to be tested. The test is of general applicability and can be used with other organisms.

The wild type of *Salmonella typhimurium* phage *P*22 is temperate. On infection, some bacteria may be lysed, but some may survive and give rise to lysogenic progeny. Lysogenic bacteria possess the ability to produce the infecting phage and are immune to subsequent infection by the phage or its mutants. Genetic control of the lysogenic condition lies in the prophage, which is presumed to be phage genetic material attached to the bacterial chromosome. Temperate phage *P*22 produces plaques with turbid centres owing to the growth of lysogenic bacteria.

Phage *P*22 mutates spontaneously to forms which produce plaques with clear centres. All mutants forming clear plaques can be classified into one of three phenotypic groups based on their ability to lysogenize[5]. These groups are called c_1, c_2 and c_3. The *c* mutations can be mapped genetically as three closely linked pseudoallelic series[6]. All the c_1 mutations fall in one series, all the c_2 mutations in a second, and all the c_3 mutations in a third. The mutations of each series are separable by recombination. These pseudo-allelic series behave like the functional units or cistrons of Benzer[7]. The alleles of the different series interact to give lysogeny, whereas the alleles of the same series do not. The *c* region is flanked by plaque-morphology loci. Fig. 1 summarizes the above in a linkage map. More complete descriptions of phage *P*22, its mutants and the methods and media used in their handling have been published elsewhere[5].

The *c* region was studied for evidence of side-chains. *Salmonella typhimurium* of strain *LT*2 is grown to concentrations of about 10^8 cells/ml. in *L* broth. The cells are washed twice in buffered saline, resuspended in one-half the original volume and aerated for 45 min. at 37°. The cell concentration is then re-adjusted to 1×10^8 cells/ml. with buffered saline. Mixtures of *c* mutant stocks, one marked with plaque morphology mutations m_3 and h_{21} and the other with the wild-type alleles of these mutations, are submitted to adsorption for 5 min. A 1 : 10 dilution is made into *L* broth containing a concentration of anti-phage serum sufficient to inactivate 99 per cent of the unadsorbed phage in 5 min. Further dilutions are then made, and after 90 min. chloroform is added to kill any surviving bacteria. Diluted samples of phage progeny are plated on indicator agar for examination.

Only the rare turbid recombinants arising by a recombination between the closely linked *c* loci in region II (Fig. 2) need be considered. (The reciprocal double-mutant recombinants are not easily detected.) These turbid recombinants are examined for additional recombinations between the clear-plaque region and the m_3 locus to the left (region I, approximately 13 units long) and the h_{21} locus to the right (region III, approximately 7 units long). Four classes of turbid recombinants are expected. Based on the relative frequencies of these four classes, a distinction between a linear vs. side-chain model can be made.

Assuming a linear structure, the four classes in order of decreasing frequencies are as listed in Fig. 2*a*. The same four classes are expected, but with different

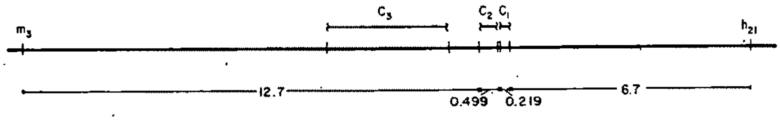

Fig. 1. Linkage map for phage *P*22

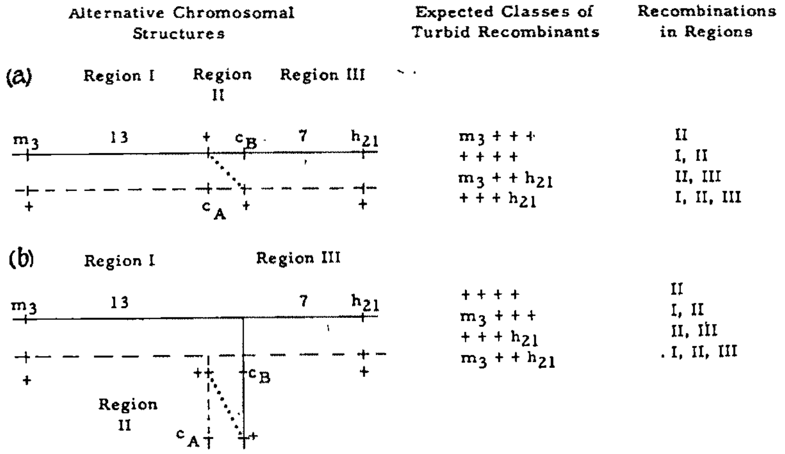

Fig. 2. Alternative chromosomal arrangements of the phage *P*22 linkage map and the expected turbid recombinant classes. The dotted lines indicate the recombinations giving rise to turbid progeny

frequencies, if the *c* alleles are arranged on the same side-chain as shown in Fig. 2*b*. (Still different but distinctive frequencies of these four classes are expected should the order of the *c* alleles be reversed.)

The rather unlikely possibility that both the c_1 and c_2 cistrons are on the same side-chain was tested by the intercistron cross, $c_2^5 \times c_1^{49}$ (Table 1). The results are in agreement with the linear model: the m_3+++ class is the major class. The two most distantly linked mutant c_2 stocks c_2^5 and c_2^{27} were crossed, on the assumption that a side-chain can be equated to an entire cistron. Again the results are in agreement with a linear structure. Similar findings were obtained from crosses between more closely linked c_2 mutants (Table 1). Finally, crosses between alleles of the smaller c_1 cistron also support the linear model (Table 1).

Table 1. CROSSES BETWEEN *C* MUTANTS OF PHAGE *P*22

Crosses		Map distance between *c* mutations	Frequency of turbid recombinant classes (per cent)				Total turbid progeny
++ Parent	m_3h_{21} Parent		m_3+++	++++	m_3++h_{21}	+++h_{21}	
c_2^5	c_1^{49}	0·843	49·3	23·8	19·5	7·4	231*
c_2^5	c_2^{27}	0·499	47·8	20·5	23·6	8·1	395†
c_2^{23}	c_2^{27}	0·333	44·8	20·2	27·0	8·0	163
c_2^5	c_2^{23}	0·276	40·8	23·9	25·4	9·9	142
c_1^{45}	c_1^{52}	0·219	55·6	18·8	17·9	7·7	117*
c_1^{65}	c_1^{49}	0·149	58·8	17·8	16·1	7·3	124*

* Sum of two independent experiments.
† Sum of three independent experiments.

The results presented do not support the idea of two genes on the same side-chain. Conceivably, some support for this hypothesis might be forthcoming from crosses between more closely linked alleles than those mentioned above. Crosses between alleles as close as 0·067 map unit suggest that linearity is still the rule. The alternative hypothesis of individual loci on individual side-chains, while not ruled out by these experiments, seems improbable. The expectation that the double-recombinant classes would increase with decreasing distance between alleles is not borne out by the results.

The apparent lack of side-chains in a phage should not be taken as too damaging to the model. A most attractive aspect of Taylor's model is the possibility that prophage establishment is the attachment of phage deoxyribonucleic acid as a side-chain to open specific points on the bacterial chromosome.

This investigation was carried out at Brookhaven National Laboratory under the auspices of the U.S. Atomic Energy Commission.

Analysis of Mixtures of Glucosamine and Galactosamine with Bakers' Yeast

STUDIES in this laboratory on the incorporation of carbon-14 precursors into corneal mucopolysaccharides necessitated the development of a method for the quantitative separation of labelled hexosamines in tissue hydrolysates. Other procedures[1-3] employing column chromatography for quantitative resolution were not suitable for the analysis of large numbers of samples. The specific fermentation by bakers' yeast of D-glucose but not D-galactose[4] and the reported phosphorylation of D-glucosamine by yeast hexokinase[5] suggested the possibility of employing whole bakers' yeast for the separation of the naturally occurring amino-sugars, D-glucosamine and D-galactosamine. Experiments with bakers' yeast revealed a quantitative removal of D-glucosamine, as measured by colorimetric procedures, and no detectable utilization of D-galactosamine. In the present communication, we wish to describe a procedure for quantitative analysis of mixtures of these two sugars. Slein[6] has reported the use of purified yeast hexokinase to distinguish between these hexosamines.

Tissue hydrolysates are first adsorbed and eluted from 'Dowex 50' (H+) resin columns in order to separate the amino-sugars from other carbohydrate components. The total hexosamine content is determined on an aliquot of these preparations by the Blix–Elson–Morgan procedure[7,8]. Another aliquot, containing up to 1 μmole of glucosamine, is placed in a volume of 1·5 ml. of water in a 25-ml. Erlenmeyer flask. 2 ml. of a yeast suspension (600 mgm. wet weight) is then added to each flask. The suspension is prepared by washing 15 gm. of *fresh* bakers' yeast (Fleischmann) four times with distilled water, with centrifugation at 4° C. between each washing. The yeast is suspended uniformly in 25 ml. of 0·1 *M* sodium phosphate buffer (*p*H 7·5) and brought to a volume of 50 ml. with water.

The stoppered flasks are incubated for 1 hr. in a constant-temperature shaker at 30° C. and 70 oscillations per min. After removing the yeast by centrifugation at 4° C., 1 ml. aliquots of the supernatant fluids are analysed for hexosamine. Centrifugation was usually repeated to ensure complete removal of the yeast. With each yeast run, a galactosamine standard (for example, 0·9 μmole) plus yeast is included in duplicate to correct for any losses by evaporation, for effects of phosphate on the colorimetric determination, and for possible non-equilibration with the large volume of yeast cells. A yeast control, which gives an optical density less than 0·01, and a glucosamine control (1 μmole) plus yeast also are included to ensure that there is complete removal of the glucosamine. More than 99 per cent of the glucosamine was removed with four different batches of fresh bakers' yeast. The commercial yeast is stable for several weeks when stored at 4° C.

The galactosamine content is calculated, employing the internal galactosamine standard, from the hexosamine concentration after yeast action. It is assumed that the extinction coefficients of glucosamine and galactosamine in the Blix test are identical[9,10]. The glucosamine content is calculated as the difference in hexosamine concentration before and after yeast action. Results of several analyses of synthetic mixtures and a comparative analysis of four blood group substances, kindly supplied by Dr. E. A. Kabat, are listed in Table 1. The limiting factor in the

Table 1. Analysis of Synthetic Mixtures of Amino-sugars and Blood-Group Substances

Added		Found	
Glucosamine (per cent)	Galactosamine (per cent)	Glucosamine (per cent)	Galactosamine (per cent)
0	100	0*	100*

20	80	21	79
37	63	35,35*	65,65*

Blood-group substances	Analysis by Leskowitz and Kabat (ref. 2)		Found*	
Hog, 16	57	43	58,57	42,43
Horse, 6–15 per cent	69	31	67	33
Saliva, W.H., 2–10 per cent	61	39	55	45
Horse, 5–25 per cent	53	47	45	55

* Samples were purified by adsorption on a 10-ml. column of 'Dowex 50' cation exchange resin (200–400 mesh, 12 per cent cross-linkage, H^+ form). The amino-sugars were completely adsorbed when placed on such columns in 2 ml. of 2 *N* hydrochloric acid. After washing the columns with water, the hexosamines were eluted with about 25 ml. of 0·75 *N* hydrochloric acid and lyophilized over silica gel–sodium hydroxide. The procedures described by Boas (ref. 8) and Roseman and Daffner (ref. 10) also should be adequate for this purpose. The blood group substances and the galactosamine sample initially were hydrolysed for 2 hr. in 2 *N* hydrochloric acid in a boiling-water bath

precision of the method apparently is the reproducibility of the Blix test. As a matter of routine, total hexosamines are determined in triplicate, and two aliquots of each sample are incubated with yeast and analysed in duplicate. 2–4 μmoles of total hexosamine (0·43–0·86 mgm. of the hydrochlorides) usually are sufficient for a complete analysis of each sample. This varies, of course, with the relative composition of the unknowns.

We wish to express our appreciation to Dr. Herbert J. Rapp for suggesting the use of a micro-organism for this separation. The work was supported by a Fight for Sight grant of the National Council to Combat Blindness, Inc., New York, and by grant *B*–141 of the National Institute of Neurological Diseases and Blindness, U.S. Public Health Service.

Contact Angles and Work of Adhesion

Because of frequent misunderstandings, we would like to emphasize that the work of adhesion W_{SL} in the equation,

$$W_{SL} = \gamma_L(1 + \cos\theta) \qquad (1)$$

which one of us has recently pleaded[1] should be called Young's equation, is the reversible work required, per square centimetre, to separate the liquid from the solid, leaving an adsorbed film in equilibrium with the saturated vapour of the liquid on the surface of the solid. This work is less than the work W_{SLO} required to separate the liquid from the solid, leaving a clean surface free from adsorbed vapour, by π_{SV^0}, the surface pressure of the adsorbed film of vapour on the solid. Calling W_{SL} in (1), W_{SLV^0}, to indicate the presence of the adsorbed film of saturated vapour,

$$W_{SLO} = W_{SLV^0} + \pi_{SV^0} \qquad (2)$$

Harkins and Livingston's remark[2] that "it is extremely unfortunate that this equation came into notice at all" was made because Harkins had previously used W_{AB} for the work required to separate two liquids A and B, with clean surfaces and surface tensions undiminished by surface films of the other liquid. Later in the same paper[3] Harkins and Livingston stated that equation (1) is correct provided that W_{SL} means W_{SLV^0}, not W_{SLO}. The importance of the adsorbed film of vapour for the magnitude of the work of adhesion is usually greater for solid–liquid than for liquid–liquid systems; and attention has frequently been directed to it, first by Harkins and Dahlstrom[4], later by Bangham and Razouk[5], Harkins and Livingston[3], and by others.

π_{SV^0}, the difference between the work of adhesion to the clean and to the film-covered surface, cannot be measured directly; but π_{SV^0} can be calculated if the adsorption isotherm of the vapour on the solid can be measured. If Γ is the amount adsorbed when the pressure of the vapour of the liquid is p, the Gibbs adsorption equation,

$$\Gamma = \partial\pi / RT\partial\ln p \qquad (3)$$

can be integrated to

$$\pi_{SV^0} = RT\int_0^{p^0}\Gamma d\ln p \qquad (4)$$

as was shown by Bangham and Fakhoury[6], and Bangham[7]; p^0 is the saturated vapour pressure of the liquid.

W_{SLV^0} is probably the work of adhesion of greatest practical importance and is by far the easiest to measure, since the part of the solid surface of importance for determining the contact angle is that immediately adjacent to the edge of the liquid, and must therefore be in equilibrium with vapour which is saturated, or nearly saturated. If W_{SLO}, which may be of greater theoretical interest, is required, the amount Γ adsorbed at a series of pressures of the vapour of the liquid must be measured and equations (2) and (4) used. On surfaces smooth enough to permit easy measurement of the contact angle, however, Γ will be so small that its measurement will usually be difficult.

THE MARK OF THE CRAFTSMAN

Send for full details now.

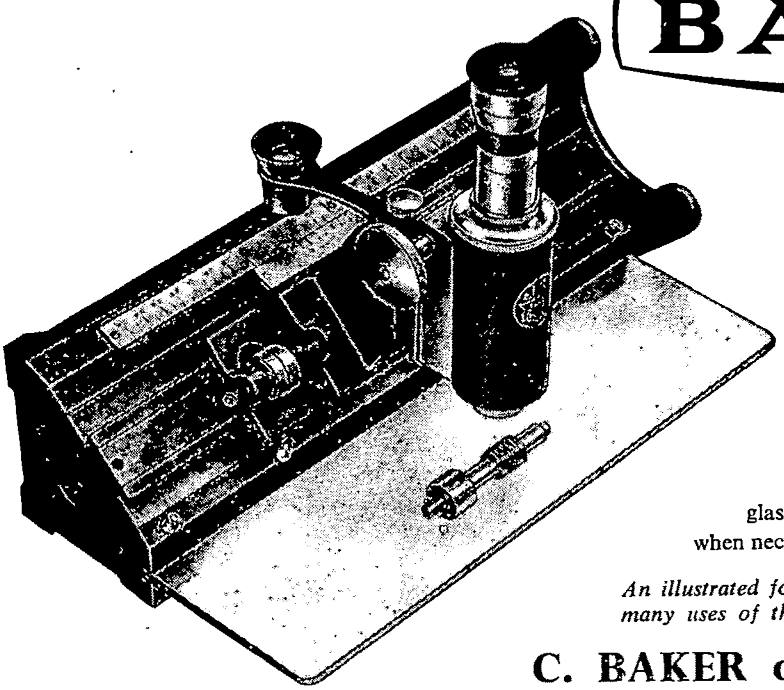
Built to meet the most exacting demands, "CYGNET" Benches, with heat and acid-resisting tops, Racks, Fume Cupboards, Cabinets and Shelving, are made in a large range of standard units or to specification.

CYGNET JOINERY LTD - DEPT. N.J. HIGHER SWAN LANE - BOLTON

TWO MODELS—
0.001 in. or 0.02 mm.

BAKER

Vernier Measuring Microscope



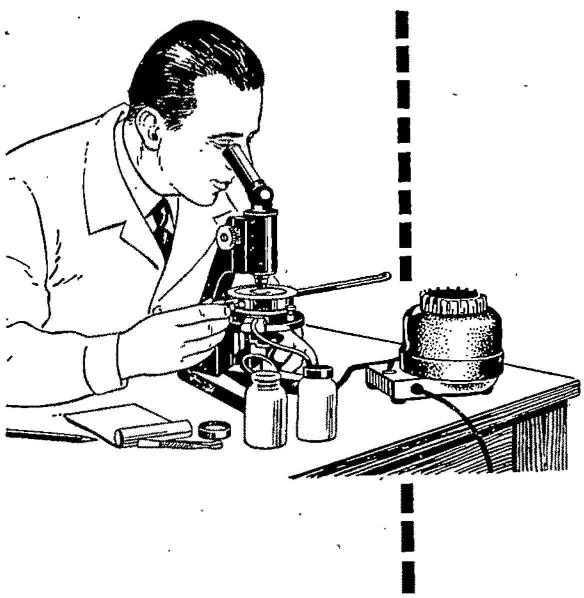
The new model of this well-tried and versatile measuring instrument is provided with a robust glass object-table which can be removed when necessary by the release of two clamp screws

An illustrated folder showing some of the many uses of the microscope is available

C. BAKER of Holborn LTD.

METRON WORKS · PURLEY WAY · CROYDON · SURREY CROydon 3845-6-7

Some applications of fusion methods



1 An unknown compound in a limited category can be identified in five minutes.

2 The purity of a compound may be rapidly determined.

3 Complete binary or ternary composition diagrams may be rapidly determined—even between unstable polymorphic forms.

4 Binary mixtures may be analysed quantitatively.

The Reichert-Kofler Hot and Cold Stage Microscope RCH is recognized as the standard equipment for chemical microscopy. The instrument is equipped with interchangeable stages to cover temperatures from −50° C. to +340° C., and a complete range of accessories is available for vacuum sublimations, the determination of refractive indices of melts, etc.

Full details on request.

for the Cleaning of Gases

Are you concerned with the cleaning of gases or liquids in any particular branch of your production plant? Here is a method which may provide a simpler, more economical means, and prove to be more efficient.

Porous Ceramics are produced in a variety of grades, from fine to coarse grain, enabling the process of filtering to be controlled accurately.

Porous Ceramic material can be supplied in any size or shape, and is chosen for the following reasons : uniformity of pore size, pore distribution and permeability ; high resistance to all acids except hydrofluoric ; cleanliness ; resistance to heat and mechanical shock ; ease of cleaning — with air, steam, water or chemicals.

The experience of our technical staff is placed at your disposal. Why not write for further information and Catalogue No. 10, to :

Royal DOULTON FILTERS

A Sensitive Micro-Spectrophotometric Method for Succinate Analysis

Assay of succinic acid by estimation of reduction of a redox dye in a succinic dehydrogenase and cyanide-poisoned system has been reported by Lardy[1] for methylene blue, and by Vishniac and Ochoa[2] for 2,6-dichloroindophenol. The disadvantage to the use of these dyes is that they are non-enzymatically reoxidized directly by oxygen and there is uncertainty concerning the end-point of the reduction of the dye and thus about the amount of succinate oxidized.

In our experiments air was displaced with argon in the solutions used and in the ground-glass stoppered Beckman cells employed. The cells were charged in an argon atmosphere in an open-top rectangular jar.

A 20 per cent succinoxidase[3] suspension which was quite stable in ice for several hours was prepared with 0·1 M phosphate buffer (pH 7·4) and homogenized in ice (using a low-speed drill press) for 7 min. with a 'Teflon' pestle glass homogenizer. This homogenization time of 7 min. was found to be the best of many intervals tested in order that sedimentation effects of tissue particles in the Beckman cells be minimized.

Each Beckman cell, including the 'blank' cell, contained 0·1 ml. 20 per cent tissue suspension (0·67 per cent after dilution in cell), 0·3 ml. 0·1 M potassium phosphate buffer (pH 7·4), 0·1 ml. 0·05 M potassium cyanide, 0·5 ml. 0·01 per cent, 2,6-dichloroindophenol dihydrated sodium salt, and 1·8 ml. glass-distilled water. It was found that the 0·67 per cent tissue suspension used in the Beckman cell media was preferable to the 2 per cent suspension used by Umbreit[3] for manometric analyses, because of both optical considerations and difficulties incurred with reduction of the dye by endogenous substrate in the succinoxidase preparation. Beckman readings showed that the endogenous reactions went to completion in about 6 min. At this point a further addition of 0·2 ml. of water was made to the 'blank' cell, and 0·2 ml. of 5×10^{-4} M sodium succinate solution (or any unknown solution) was added to all other cells. The 'blank' cell was adjusted to a high enough scale reading so that negative readings need not be taken on the other cells.

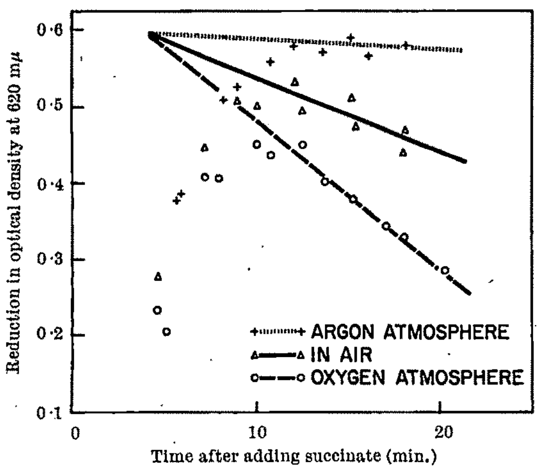

Fig. 1. Decreases in density relative to the 'blank' cell during the stated periods of incubation in systems varying from 0 to 100 per cent saturation with oxygen. The straight lines coming to a common point represent extrapolation of the slopes of the three curves

The relative effects of atmospheres of argon, air and oxygen on changes in optical density after addition of the stated amount of sodium succinate in each system are compared in Fig. 1. The Beckman density readings refer to relative decreases in density from the 'blank' cell. It is clear from these comparisons that by substituting argon for oxygen, reversal of the reduction of the dye through direct re-oxidation is avoided, and a more valid measurement of succinate content thus achieved. By extrapolating the slopes of the three curves in Fig. 1, and observing a common point of intersection, one again may see the desirability of working in the anaerobic system described in order to achieve maximum effects. The sensitivity of the argon system is such that each 0·01 Beckman density unit is proportional to 0·00167 μmole of succinate. Accuracy to the nearest 0·01 μmole of succinate may thus be achieved.

Formation of Carbon by Decomposition of Carbon Suboxide at 750-780° C.

The recent communication by Deitz and Prosen[1], which suggests that carbon suboxide is the means of transport of carbon in the system carbon monoxide–graphite at 450° C., prompts us to record some observations on the decomposition of carbon suboxide.

During attempts to prepare carbon suboxide by the pyrolysis of diacetyl tartaric anhydride[2] at 750–780° C., the formation of lustrous flakes was observed in the hot part of the reactor. This material was probably formed by polymerization of carbon suboxide, followed by decomposition of the polymer[3].

These lustrous flakes (0·5 per cent w/w of the diacetyl tartaric anhydride initially present) were shown by chemical and spectrochemical analyses to be essentially carbon, with about 1 per cent of hydrogen and of oxygen; trace impurities (silicon, aluminium, iron and magnesium) were present. A Debye–Scherrer X-ray diffractogram showed a strong 002 band and weak 100 and 110 bands. The optical reflectance measured in cedar wood oil was 18 per cent, a value higher than that (about 11 per cent[4]) reported for natural graphite.

It is noteworthy that instead of a soot, a hard graphite-like material was deposited at these low temperatures.

Wave-length Effect in Flash Photolysis

When oxygen-free solutions of methylene blue or thionine in dilute sulphuric acid are subjected to flash photolysis using orange-red light filtered from a krypton- or xenon-filled flash-tube, reversible bleaching of the dyestuffs occurs. The bleaching is accompanied by increased absorption in the region 360–440 mμ where the dyestuffs themselves absorb very weakly. The transient species responsible for this absorption have the appearance of being triplet levels of the dyestuffs, disappearing with life-times of less than 30 μsec. The same species are also produced when the light of the flash is filtered through Chance *OX*7 glass (transmission approximately 250–390 mμ).

When the unfiltered light from the flash-tube is used for excitation, there are formed, in addition to the 'triplet' species, other species which disappear much more slowly (half-life of the order 0·5 msec. under the conditions of experiment). From the limited information at present available, the second type of species appears to be similar to the semiquinones which are formed by reduction of the dyestuffs when their solutions are flashed with orange-red light in the presence of 0·1 *M* ferrous sulphate (in the presence of the ferrous sulphate the 'triplet' species are no longer evident). If the long-lived species are indeed the semiquinones of the dyestuffs, it would appear that water itself can act as the reducing agent when short wave-length ultra-violet light is used for excitation.

Whatever the true nature of the long-lived and the short-lived species, they are formed by independent processes, the long-lived species by wave-lengths shorter than 250 mμ and the short-lived species by longer wave-lengths. These observations may be compared with the results obtained by Bridge and Porter[1] in the flash photolysis of solutions of duroquinone using the full light of the flash-tube. They observed the independent formation of both triplet and semiquinone radical, and it is interesting to speculate whether their results can be explained in terms of a similar wave-length effect, since many of the solvents they used are transparent to wave-lengths shorter than 250 mμ. Before the behaviour of duroquinone can be fully established, therefore, it would be necessary to carry out experiments with filtered exciting light. This same precaution naturally applies to all flash-photolysis work, and is of course particularly important in those investigations where photosensitization to daylight is in question.

The investigation of the effects observed with methylene blue and thionine is being continued and will be reported in detail elsewhere.

---

[1] Bridge, N. K., and Porter, G., *Proc. Roy. Soc.*, A, 244, 259, 276 (1958).

The fact that primary photochemical processes may depend on wave-length is, of course, well known, and investigations of wave-length effects in flash photolysis have previously been carried out[1]. Our work on duroquinone was concerned with the identification of the intermediates and of the kinetics of their reactions, which are, for any given intermediate, independent of wave-length.

A study of the effect of wave-length on the primary products of photolysis of duroquinone is now in progress. Mr. Michael Reed has found that when a glass filter (cut-off at 300 mμ) is used, triplet-state absorption in liquid paraffin and formation of semiquinone radicals in ethanol are still observed, though the concentration of radical is considerably reduced. Some reduction in concentration is to be expected on the basis of reduced light absorption, since the maxima of duroquinone lie at 270 mμ ($\log \varepsilon = 4 \cdot 3$), 340 mμ ($\log \varepsilon = 2 \cdot 3$) and 450 mμ ($\log \varepsilon = 1 \cdot 4$).

If Parker's assignments are confirmed, the methylene blue system provides another example where radical formation does not occur principally via the triplet state. So far as dependence on wave-length is concerned, it will be necessary to have observations on the quantity of light absorbed in each experiment and the effect of intensity, since both wave-lengths and intensity have been varied and the observed differences may be attributed to either.

A Methane-Conversion Detector for Gas Chromatography

Detectors most commonly found in gas chromatographic instruments involve the use of thermal conductivity cells. Such cells, particularly those of the thermistor type, decrease in sensitivity with increasing temperature. Since it is necessary sometimes to heat the cell to prevent condensation effects of high-boiling materials leaving the chromatographic column, new approaches to this problem were sought. Martin and Smart[1] were successful in improving the sensitivity by converting the resolved compounds as they emerged from the chromatographic column into carbon dioxide and water, and detecting the carbon dioxide by means of an infra-red gas analyser. This procedure was repeated by Green[2] using a thermal conductivity cell to measure the carbon dioxide ; however, loss of resolution and band spreading detracted from the increased sensitivity obtained. Green improved this technique by passing the water formed in the combustion process through a hot tube containing iron powder, thereby producing hydrogen, which was detected in the thermal conductivity cell. Nitrogen was the carrier gas.

The procedure presented here makes use of a small tube containing a 'hydrocracking' catalyst at the exit end of the chromatographic column. As each compound emerges from the column, it is converted to methane and water. The water is removed in a drying column, and the methane is measured by a thermal conductivity cell. Hydrogen is used as the carrier gas.

The methane converter consists of a tube of 'Pyrex' glass, 24 cm. long and 5 mm. in diameter, filled with a nickel catalyst of 30–60 mesh. The tube is kept at about 350–450° C. by means of a heated nichrome coil.

This procedure has the following advantages :

(1) Increased sensitivity is obtained by being able to operate the thermal conductivity cell at ambient temperatures, since only methane is being detected.

(2) Calibrations due to differences in thermal conductivities of the separated components are unnecessary; however, the carbon number effect must be considered.

(3) The method is applicable to other detectors where hydrogen is used as a carrier gas, such as the hydrogen flame detector[3].

(4) It offers a convenient way of analysing aqueous solutions of aldehydes, alcohols and ketones, since these are easily converted to methane and water over the catalyst. The water may be removed by a suitable drying column containing, say, calcium sulphate.

Compounds susceptible of complete 'hydrocracking' to methane have been analysed using hydrogen as the carrier gas. The methane conversion procedure has been used for mixtures containing (*a*) C_1–C_{12} paraffins and olefins, (*b*) C_5–C_8 naphthenes, and (*c*) C_2–C_5 aldehydes, alcohols and ketones. The catalyst remained active for more than 100 samples.

Contamination of Surfaces by Conductivity Water from Ion-exchange Resins

IN several recent papers research workers in surface chemistry have reported using ion-exchange resins as a convenient means of removing electrolytes—in place of dialysis in the treatment of inorganic sols, for example, and to obtain 'conductivity water' for studies of dilute detergent solutions or monolayers on a Langmuir trough. For most purposes where 'pure' water is needed, even in colloid chemistry, the water obtained by passing ordinary distilled water through a 'mixed-bed' ion-exchange resin column is perfectly satisfactory, but for any critical work in surface chemistry it is not. The dangers are shown by the following experience.

In a study of the surface charge on finely divided particles by the micro-electrophoresis method, water from a mixed-bed resin column was used throughout for washing the cell and preparing the solutions. It had a specific conductivity of 0·3 micromho cm.$^{-1}$ and would normally be considered of good quality compared with ordinary distilled water, which gives about 3·5 and contains traces of copper, etc. A series of determinations with different dilute salt solutions gave what seemed to be satisfactory results until similar measurements were made with dilute hydrochloric acid. As the concentration of hydrochloric acid was increased from 10^{-6} to 10^{-4} *N*, the electro-osmotic flow along the glass walls of the cell fell to zero and then reversed in direction; that is to say, the glass became positively charged. (The suspended particles on the contrary remained negatively charged.) The anomalous charge on the glass was eventually ascribed to contamination by traces of a weakly basic substance from the resin column—almost certainly soluble polymer fragments released from the nitrogenous anion-exchange resin.

The presence of traces of organic impurities in water from resin columns is very difficult to check by direct analysis, but it is well known that water which has stood for some hours in a mixed-bed shows a relatively high conductivity. (Several 'bed-volumes' must first be run off to waste.) Clearly, this cannot be due to micromolecular electrolytes since these are effectively removed by the resins. It must be caused by colloidal polyelectrolytes, released by the resins and unable to penetrate into the resin particles of opposite charge because of size.

The purity of water from a mixed-bed column is therefore dependent on the time of contact with the resin. Rapid flow through a short column may allow electrolytes present in the feed water to 'break through', but slow flow through a long column may introduce organic polyelectrolytes.

Conductivities as low as 0·065 micromho cm.$^{-1}$ at 25° C. have been reported[1] for water from a mixed resin bed in favourable circumstances, and this is remarkably close to the theoretical value of 0·055 at 25° C. for perfectly pure water; but it is common experience to find values in the range 0·1–0·5 micromho cm.$^{-1}$. This conductivity value is a dangerous index. It can easily be dismissed as due to an 'insignificant trace' of electrolyte (for example, 10^{-6} *N* potassium chloride), but in fact may indicate a considerably higher (though quite unknown) amount of surface-active polyelectrolytes which may accumulate by adsorption on suitable surfaces.

With improvements in the stability of ion-exchange resins and careful attention to flow conditions, it may become possible to reduce the danger to almost negligible levels. But at the present time it is clearly advisable to avoid the use of resins entirely in all critical work in surface chemistry where small surface areas are concerned. Repetition of the experiments mentioned above, but using triple-distilled water finally condensed in silica, gave significantly different results for the suspended particles as well as for the glass surfaces.

Void Nucleation Sites in Creep of Metals

FOR metals undergoing slow deformation at elevated temperatures, it has been shown that nucleation of voids by condensation of lattice vacancies requires either a very high concentration of excess vacancies (approximately 100 times the equilibrium value[1]), or very high concentration of stress[2]. It appears that such concentrations of vacancies are never approached even at high rates of deformation[3], so that voids must form at points where sufficiently large stresses develop. It has been suggested that ledges on a sliding grain boundary may provide these sites for nucleation.

The nature of ledges in the boundary is uncertain. Gifkins[4] suggested that they result from slip in one grain on planes almost perpendicular to the boundary being accommodated by slip in the adjoining grain. He believed that this mechanism required a pile-up of dislocations at the end of the slip plane. McLean[5] considered that the ledges are formed by glide of dislocations to the boundary. However, in these cases it might be expected that an increase in temperature or decrease in rate of strain (that is, increased duration of test) would facilitate such stress-relieving processes as movement of the ledge itself[5], or boundary migration, which would flatten out the ledges. Thus it appears that to form holes the ledges must be locked in position.

An alternative possibility is that the ledges causing formation of voids cannot be flattened out by migration due to their inherent structure. Thus suppose that a dislocation with a screw component normal to the plane of the boundary intersects the latter, then a step will be produced at the boundary similar to the steps observed in crystal growth. Such steps would inhibit sliding[5] and provide sites for the development of the high stress concentrations necessary for void nucleation. It may be possible for a number of nearby screw dislocations of the same sign to interact to form steps many atomic distances high. Dislocations of opposite sign emerging into the grain boundary near each other may combine to form terraces.

If the above mechanism of hole formation be correct, the ease of nucleation in a pure metal should be related to the size of the dislocation network, that is, to the number of sites available. In metals such as aluminium, which has non-extended dislocations, grain boundary steps might be annihilated by cross-slip of nearby dislocations to produce atomically flatter surfaces, as shown by Anderson and Dawson[6]. This would account for the absence of visible formation of voids in aluminium of very high purity fractured under creep conditions. In less pure metals or alloys, locking of the screw dislocations by impurities or by edge dislocations already anchored will be an important factor in causing formation of voids. The difficulty encountered in improving resistance to creep without adversely affecting ductility might also be due to the dislocations giving ledges at the boundary being anchored as a result of hardening within the grains.

Fracture Markings in Polymethyl Methacrylate

THE surface markings on the fracture surfaces of glass and plastics show that the fracture is discontinuous and that patterns are formed through secondary initiations ahead of the main fracture front which unite to form the completed fracture surface[1-3]. Intersection of an isolated secondary fracture with the main crack front usually produces a parabolic marking[2,4]. Such centres of secondary initiation are microcracks, stress-raising discontinuities, or inclusions. New evidence has been obtained of the importance of such flaws in fracture behaviour and patterning in polymethyl methacrylate.

The tensile fractures of conventional test specimens of the material in cast and (dental) moulded form have been found to show striking differences. The fatigue fractures are likewise dissimilar. These differences are little affected by ambient conditions and have been ascribed to structural effects. The cast material, which was obtained commercially ('Perspex') and from syrup initiated by benzoyl peroxide, is macroscopically homogeneous, whereas the material moulded by dental techniques has a grain structure consisting of the original polymer particles, which are approximately spherical, embedded in a matrix of newly-formed polymer. This structure was clearly revealed by etching with 80–90 per cent nitric acid, which preferentially attacked the matrix material.

The tensile fracture (A.S.T.M. *D*638–52*T*) of the cast sheet ('Perspex'), both at 20–22° C. and 50–65 per cent relative humidity and at 37° C. and 100 per cent relative humidity, showed a typical cleavage appearance similar to that described by Kies[1] and George[2]. The smooth mirror-like surface had a number of parabolic markings (Fig. 1*a*). In contrast, the dental polymer showed a much more complex and discontinuous fracture (Fig. 1*b*). A small mirror-like origin was the centre of a number of rough concentric ridges made up of three-dimensional crack systems separated by smoother regions which themselves contained extreme complexity of markings. The fracture markings of cast sheet made from syrup (probably containing dust particles) were intermediate between these extremes, showing two or three ridges on a fairly smooth surface. Lowering the temperature and increasing the rate of loading caused the appearance of the fracture in cast sheet to approach that of the moulded material, but even at –60° C. the 'Perspex' fracture did not attain the complexity of the latter.

The long-term fatigue fractures (plane bending, 1–5 c./s., in room conditions, and at 37° C. and 100 per cent relative humidity) were different in morphology also. 'Perspex' showed a mirror-like origin and smooth surface, while the moulded polymer showed an area of origin containing propagation markings (Kies's "river systems") which gave place to a smoother surface on which the grain structure was delineated by many parabolic markings with heads concentrated at grain boundaries. The service

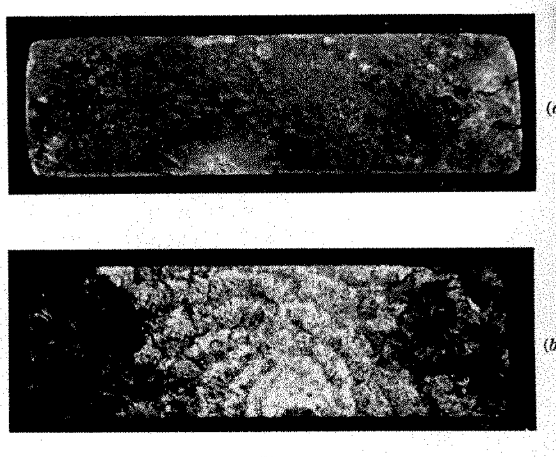

Fig. 1

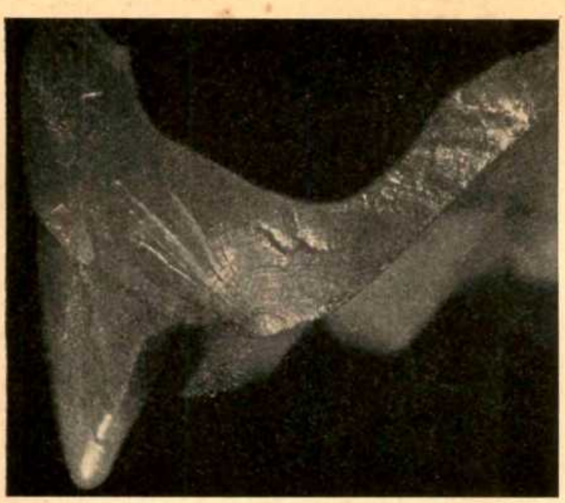

Fig. 2

fracture of polymethyl methacrylate upper dentures (Fig. 2) is similar, but shows the usual arrest markings.

The differences in tensile, and in fatigue, fracture can be explained in terms of the load magnitude, the flaw distribution, and their effect on crack propagation.

The tensile crack starts at some surface fault (occasionally internally) and rapidly increases in velocity as the stored elastic energy diminishes[2,5]. Where there are few major flaws as in 'Perspex', few secondary cracks are produced and these become enveloped quickly. Since the stress field contracts and crack velocity increases, however, the final fracture becomes complex[6]. In the moulded material the large number of major flaws results in the formation of multiple cracks at some critical velocity of the crack-front. The diminution in stored elastic energy results in a momentary hesitation while the energy builds up again, since more energy is required to start a crack than to propagate it[7]. Repetition of this cycle gives the regular discontinuous appearance.

In the case of fatigue failure, the initial cleavage fracture which occurs quite early in the test is propagated only slowly. Since the overload is small in the case of the moulded material, only the major flaws at grain boundaries act as nuclei.

This explanation is substantiated by the change in patterning which takes place if the cast polymethyl methacrylate is pigmented, when the tensile fracture becomes discontinuous as in Fig. 1*b*. A similar phenomenon has been observed in extruded polystyrene rod. Thus the mode of fracture in these materials is dependent on the number and distribution of flaws.

It is hoped that a fuller account of this work will be published elsewhere.

Scintillation Counter for measuring Radioactivity of Vapours

The gas chromatographic technique of James and Martin[1,2] is often used to fractionate substances biosynthesized from precursors labelled with carbon-14. For the assay of carbon-14 in the various fractions it is necessary, at present, to collect the fractions individually and then transfer them to a counting device. Direct measurement of the radioactivity of vapours as they leave the chromatographic column would save much time and labour and improve accuracy.

We have devised an instrument which counts the carbon-14 content of vapours emerging from a gas chromatographic apparatus parallel with the analytical chromatographic record. In principle, the chromatographic vapours are condensed into a circulating liquid phosphor: a solution of diphenyl oxazole in xylene. The scintillations excited in the phosphor by the carbon-14 are detected with a photomultiplier.

Fig. 1 illustrates the instrument diagrammatically. The vapours and carrier gas (nitrogen) flow through capillary tube *A*, which is heated electrically to the temperature of the column; then they bubble into the liquid phosphor, which is kept in vigorous circulation around the circuit *BCDE* by the bubbles of carrier gas rising in tube *B–C*. As the vapours are soluble in xylene and have high boiling points they are stripped from the carrier gas on entering the liquid phosphor. Jacket *F* cools the xylene on its path from *A* to the counting cell *S*. This cell is a cylindrical cavity (1 cm. deep, 15 ml. capacity) formed by pressing a polyethylene cup over the window-end of a photomultiplier. Thus the scintillations produced in the phosphor are 'seen' directly by the photomultiplier, there being no loss of light due to interfaces between the phosphor and the photomultiplier.

The phosphor is introduced and removed through a thin polyethylene tube, inserted into opening *X*, and extending to point *E*. The opening *X* also allows the carrier gas to escape. A combined support and lead shield holds the photomultiplier horizontally, the whole assembly being placed in a lagged and light-tight box. Cooling liquid at about 0° C. is pumped through tubes in the side of the box and circulated through the jacket *F* and the photomultiplier support.

Pulses from the photomultiplier are amplified and fed into a rate-meter and recorder. The record of

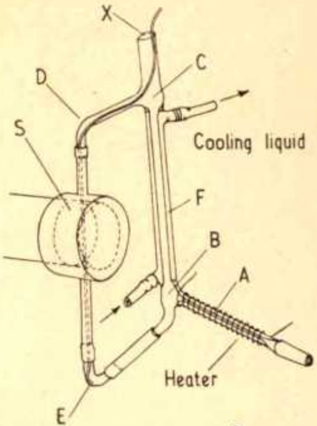

Fig. 1. Instrument for measuring radioactivity of vapours

radioactive counts is of integral form, identical in shape with the records of chromatograms obtained from the automatic titration instrument of James and Martin[1].

By injecting a known amount of fatty acid labelled with carbon-14 into the phosphor, the overall efficiency of counting was found to be approximately 30 per cent, which is satisfactory as the photomultiplier 'sees' only about two-thirds of the total volume of phosphor. The background count, including electronic noise, was 3·8 counts/sec.

A full description of the technique and constructional details of an improved apparatus will be published elsewhere.

We wish to thank Dr. G. Popják for suggesting the technique and for his advice and encouragement, and Messrs. E. K. Cole for the loan of the photomultiplier.

Counting Error due to Overlapping Particles in Thermal Precipitator Samples

THE thermal precipitator[1] is widely used as a standard instrument for sampling dust clouds. The dust from a measured volume of air is deposited on glass slides and is afterwards counted under a microscope.

Some particles consist of several smaller ones clumped together and these 'aggregates' are counted as single particles. Other particles are deposited so that they overlap ones already deposited, producing spurious aggregates. These cannot be distinguished from true aggregates and consequently the dust concentration is under-estimated. In the many previous tests of the thermal precipitator the magnitude of this error does not seem to have been investigated.

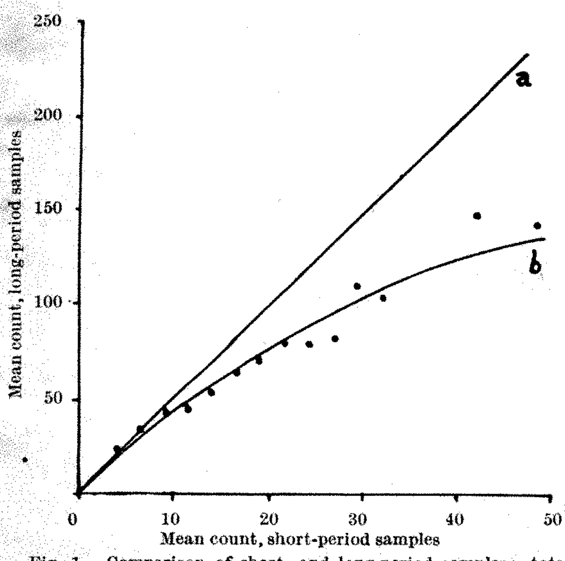

Fig. 1. Comparison of short- and long-period samples; total number of particles per 20μ traverse; *a*, no overlapping; *b*, fitted curve

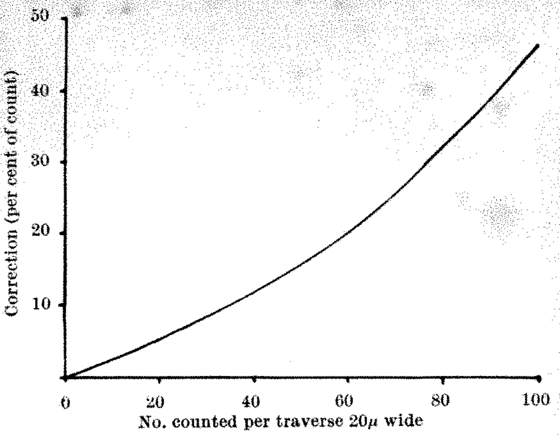

Fig. 2. Correction to be added to the count

Two thermal precipitators were placed in a colliery and pairs of samples were taken in which one of the instruments samples for five times as long as the other. A comparison of corresponding mean counts from the two instruments is given in Fig. 1. The short-period counts were grouped and the corresponding long-period means calculated. In the absence of overlapping the long-period counts would be five times the short-period counts, shown by the straight line. In fact they were less, by an amount which increased with the density of the deposit, indicating that a considerable amount of overlapping occurred in the denser samples.

The mean projected area of the particles was $18{\cdot}6\mu^2$. With finer dusts the effect of overlapping will be smaller.

A curve was fitted to the results using an equation similar to those derived theoretically by other workers[2]. From this curve we can estimate the correction to be added to the number counted to make it equal to the number deposited (Fig. 2).

The results show that with sample densities of 25–50 particles per 20-μ traverse, the true dust concentrations of the coal dust cloud are between 5 and 15 per cent higher than those estimated from the counts. Other workers have recommended densities several times greater than this[1,3]. If such densities were in fact used, the overlap error would be very large. The error can be reduced by using very low densities, but the extraneous contamination then becomes an increasingly large error. Consequently it does not seem to be possible in practice to avoid the error introduced by overlapping particles when sampling airborne dust similar to that occurring in this coal mine. The value of the thermal precipitator as a standard reference instrument in coal mines is therefore open to doubt and needs re-investigation against an absolute standard such as a sedimentation cell.

A full report of this work will be published elsewhere.

FORTHCOMING EVENTS

Wednesday, July 16

International Palæontological Union (in Room 128, Royal School of Mines, Prince Consort Road, London, S.W.7), at 4 p.m.—General Meeting. (Second General Meeting on July 17.)

Friday, July 18

Biochemical Society (in the Department of Biochemistry, The University, Sheffield), at 2 p.m.—375th Meeting.

Saturday, July 19

British Psychological Society (at Birkbeck College, Malet Street, London, W.C.1), at 2.30 p.m.—Prof. E. N. Sokolow (University of Moscow): "Objective Study of Hearing Disorder".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer (with a first- or second-class honours degree and experience in lecturing in soil science and agricultural chemistry) in Soil Science and Agricultural Chemistry at Shambat Agricultural Institute, Education Division, Ministry of Agriculture, Sudan—The Sudan Embassy, Personnel Section, Cleveland Row, London, S.W.1, quoting Ref. "Lecturer Soil Science 4/447" (July 15).

Senior Lecturer or Lecturer (male, British, with a first- or second-class honours degree in mechanical engineering) in the Applied Mechanics Department; and a Senior Lecturer or Lecturer (male, British, with an honours degree or equivalent in electrical engineering, and preferably special experience in telecommunications) in the Physics and Electrical Engineering Department—The Director of Studies, R.N. College, Greenwich, London, S.E.10 (July 18).

Area Chief Scientist (with a good degree (or equivalent) in chemistry, physics or fuel technology and wide industrial experience) in the Cannock Chase Area—The Divisional Chief Staff Officer, West Midlands Divisional Coal Board, Himley Hall, Dudley, Worcs, quoting NA (July 19).

Assistant, Grade B (preferably with experience in industry, teaching and/or research), in Inorganic Chemistry—The Principal, Nottingham and District Technical College, Burton Street, Nottingham (July 19).

Assistant Lecturer, Grade B (with professional qualifications in biology and preferably the ability to teach microbiology or bacteriology) in Biology at the City College of Technology, Byrom Street, Liverpool—The Director of Education, City of Liverpool Education Committee, 14 Sir Thomas Street, Liverpool 1 (July 19).

Assistant Lecturer in the Department of Numerical Automation, with special reference to electronic calculation and numerical analysis—The Secretary, Birkbeck College (University of London), Malet Street, London, W.C.1 (July 19).

Assistant Engineers (with the H.N.C. or a degree, or other suitable technical qualifications in physics, applied physics and mathematics, or electronics, and preferably some practical experience) in the Design Section of the Nuclear Power Plant Design Branch at Headquarters, London, to work on problems of radiation levels in relation to health physics—The Chief Personnel Officer, Central Electricity Generating Board, 24–30 Holborn, London, E.C.1, marking envelope "Confidential" and quoting Ref. N/173 (July 21).

Assistant Lecturer in the Department of Chemistry and Biochemistry—The Dean, St. Thomas's Hospital Medical School, London, S.E.1 (July 25).

Lecturer (preferably with qualifications in mathematical statistics) in Statistics—The Secretary, The University, Aberdeen (July 25).

Lecturer (with postgraduate research experience and preferably previous academic teaching experience) with special interests in Physical-Organic Chemistry—The Clerk to the Governors, Chelsea College of Science and Technology, Manresa Road, London, S.W.3 (July 26).

Regius Chair of Botany in the University of Edinburgh—The Private Secretary, Secretary of State for Scotland, St. Andrew's House, Edinburgh 1 (July 28).

Research Assistants (with, or expect shortly to possess, an honours degree in chemistry, or A.R.I.C.) in Organic and Organometallic Chemistry—The Registrar (Room 22, O.R.B.), The University, Reading (July 31).

Assistant Professor of Metallurgy—Head of the Department of Mining and Metallurgy, University of Alberta, Edmonton, Alberta, Canada (August 1).

Lecturer in Pharmacology—The Registrar, Trinity College, Dublin (August 1).

Lecturer in Education at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, August 4).

Lecturer (qualified in either mycology and plant pathology, or physiological or biometrical genetics) in Botany; a Lecturer or Senior Lecturer in Fluid Dynamics; and a Lecturer (preferably strong in applied mathematics or physics and interested in fundamental geophysics rather than geophysical prospecting) in Geophysics at the University of Tasmania, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, August 4).

Professor of Botany, a Professor of Chemistry, a Professor of Geology, a Professor of Physics, and a Professor of Zoology—The Registrar, Canberra University College, Canberra City, Australia (August 8).

Senior Lecturer in Histology, and a Lecturer in Anatomy, at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, August 11).

Physical Metallurgist or Metal Physicist (Principal Scientific Officer) (with a first- or second-class honours degree in metallurgy or comparable qualification, and at least three years relevant postgraduate experience) with the Admiralty at Rosyth—Civil Service Commission, 30 Old Burlington Street, London, W.1, quoting S.4858/58 (August 12).

Chair of Geography in the University of Adelaide, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, August 13).

Lecturer or Senior Lecturer in Mathematics at the University of New England, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, August 15).

Assistant Biochemist (young graduate with a good honours degree in chemistry or equivalent qualification, and preferably with analytical experience) in the Department of Pathology, for duties which include participation in research, particularly in the field of steroids—The Group Secretary, Queen Elizabeth Hospital for Children, Hackney Road, London, E.2.

Biochemist (medical qualification not essential), to conduct research in the field of rheumatic diseases—The Director, Rheumatic Unit, Northern General Hospital, Ferry Road, Edinburgh 5.

Joseph Lucas Fellow, for research in the field of Electrometallurgy, with emphasis on the growth, structure and mechanical properties of electrodeposits—The Registrar, The University, Edgbaston, Birmingham 15.

Metallurgist, Chemist or Physicist (graduate, preferably with language knowledge) in the Information Department, for work on all aspects of recording and transmission of information on extraction, fabrication and use of non-ferrous metals—The Secretary, British Non-Ferrous Metals Research Association, Euston Street, London, N.W.1.

Scientific Officer (with a good science degree, a reading knowledge of two European languages (preferably other than French or German), the ability to write good English and preferably a knowledge of soil science and plant physiology), for work in a scientific information service involving abstracting and indexing—The Director, Rothamsted Experimental Station (Commonwealth Bureau of Soils), Harpenden, Herts.

Technician (with H.N.C. or equivalent in chemistry and/or physics, and preferably skill in laboratory techniques, for example, glass-blowing or electronics), to carry out experimental work and assist in the construction and maintenance of apparatus in the Department of Chemical Microbiology—The Secretary, National Institute for Research in Dairying (University of Reading), Shinfield, Reading, quoting Ref. 58/5.

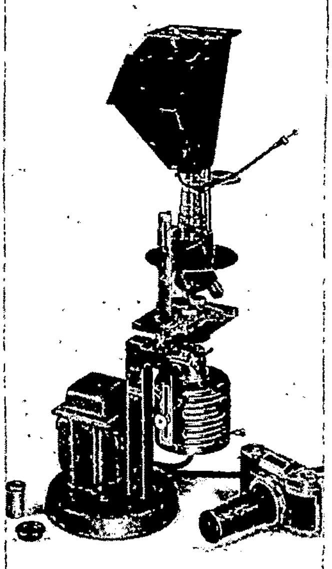
BRITEX PROJECTION MICROSCOPE with CAMERA ATTACHMENT



Illustrates still another purpose to which this unit can be successfully applied and which clearly demonstrates the instrument's versatility and usefulness in industry, research and education.

FIVE MAIN USES:
- Projection in daylight.
- Projection on to a screen.
- Drawing of specimens.
- Examination of specimens in liquids.
- Use as an ordinary microscope.

Fuller details gladly sent on request.

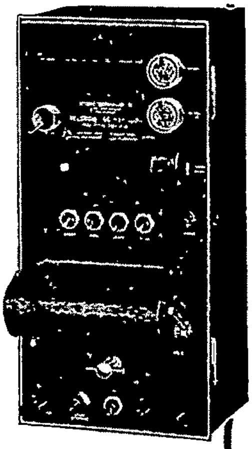
BER 62
RECORDING OSCILLOGRAPH

The seismic investigations carried out by the British Commonwealth Transantarctic Expedition were recorded by means of the BER 62 Recording Oscillograph Camera and Seismic Geophones. The instruments worked perfectly under these extremely difficult conditions, showing outstanding ruggedness and reliability.

The BER 62 Oscillograph Camera has been specially designed for portability in geophysical surveys, using the seismic method; it records simultaneously 25 independent traces on 6 in. photographic paper timed by a synchronous motor-slotted drum system driven by a precision tuning fork. The BER 62 is craftsman-built from the highest quality components and materials.



CAMERA

Up to 25 pencil-type galvanometers adjustable vertically and horizontally. Timing by lines across trace every hundredth second. Each fifth line bolder.

Galvanometers 125 c/s. 13 ohms coil. Sensitivity 4"/mA at 12" radius.

Camera suitable for daylight loading and removable record magazine fitted with paper knife.

Rugged, gasket sealed, stainless steel case affords adequate protection.

Size 18" x 8½" x 9¾". Weight 40 lbs.

We market a complete range of equipment for seismic exploration, including Power Units, Amplifiers, Cables and Blasters.

Please write for details of this Oscillograph, and of the range of seismic instruments we have to offer.

LECTURES AND COURSES

CHELSEA COLLEGE OF SCIENCE AND TECHNOLOGY

SANDWICH COURSE IN CHEMISTRY

The Sandwich Course in preparation for the examination leading to Graduateship of the Royal Institute of Chemistry commences on September 22, 1958. The course (works based) is of four years' duration and involves six-months' study at College each year. The normal requirements for admission to the course will be successes at " A " Level (G.C.E.) or comparable examinations, in chemistry, physics and mathematics and three suitable ordinary level subjects.

Inquiries from industrial firms, research organizations, and government departments will be welcomed. Particulars from the Secretary, Chelsea College of Science and Technology, Manresa Road, S.W.3.

CHELSEA COLLEGE OF SCIENCE AND TECHNOLOGY

MANRESA ROAD, S.W.3.

DEPARTMENT OF BOTANY AND ZOOLOGY

(A) Courses in general and advanced Microbiology will begin on October 3, 1958. (B) Course of lectures, with practical work on " Metabolism of Micro-organisms " on Mondays 6–9 p.m. beginning September 29, 1958. Tuition fees: (London students), Course A (October to June), 40s. (first year); 40s. (second year). Course B (September to Easter), 40s.

Intending students should write to Head of Department of Botany and Zoology, before August 31, 1958. Enrolment September 17, 6–7.30 p.m.

SURREY EDUCATION COMMITTEE

KINGSTON TECHNICAL COLLEGE
FASSETT ROAD, KINGSTON-UPON-THAMES
DEPARTMENT OF CHEMISTRY, BIOLOGY, AND GEOLOGY

Applications are invited for entry to the three-year full-time course in preparation for the London University.

B.SC. SPECIAL DEGREE IN GEOLOGY.

The course re-opens in September, 1958. Form of application for entry and further particulars obtainable from the Principal at the above address.

OFFICIAL APPOINTMENTS

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL

LONDON, S.E.1

Applications are invited for the post of Assistant Lecturer in the Department of Chemistry and Biochemistry. The post will be tenable from October 1, 1958, or earlier if the successful candidate is available. Commencing salary, according to qualifications and experience, in the scale £850 by £50 to £1,050 per annum plus London allowance of £60. Membership of the F.S.S.U. and children's allowance scheme.

Applications, giving details of qualifications and the names of two referees, should be submitted by July 25, 1958, to the Dean, St. Thomas's Hospital Medical School, London, S.E.1, from whom further information may be obtained.

UNIVERSITY OF SOUTHAMPTON

Applications are invited for Research Studentships in Organic and Inorganic Chemistry, leading to Ph.D. Applicants with G.R.I.C. will be considered.

Send details of qualifications and names of two referees, to the Secretary and Registrar, the University, Southampton.

D.S.I.R. REQUIRES SCIENTIFIC OFFICER at Building Research Station, Garston, Watford, Herts, for work in section dealing with information and publicity through exhibitions, press, etc., secretarial work for home and European scientific committees, patents, and general central administration on scientific matters. Qualifications: first- or second-class honours degree in mathematics, science, or economics. Salary range: (men) £595 to £1,050. Allowance for National Service and postgraduate experience. Normal prospects of promotion in mid-thirties to Principal Scientific Officer (salary range £1,370 to £1,950). Forms from Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1 (quote A.242/8A.)

UNIVERSITY OF SYDNEY

AUSTRALIA

LECTURESHIP/SENIOR LECTURESHIP IN AERONAUTICAL ENGINEERING

Applications are invited for the above-mentioned position. The successful applicant will be expected to lecture in the subject of Aircraft Structures. Some experience in the field of aeroelasticity is desirable but not essential. The salary for a Lecturer will be in the range £A.1,500 by £A.90 to £A.2,100 per annum; for a Senior Lecturer in the range £A.2,200 by £A.80 to £A.2,550 per annum. In each case cost of living adjustment will be allowed. The salary will be subject to deductions under the State Superannuation Act. The commencing salary will be fixed according to the qualifications and experience of the successful applicant. Under the Staff Members' Housing Scheme, in cases approved by the University and its Bankers, married men may be assisted by loans to purchase a house.

Further particulars and information as to the method of application may be obtained from the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1. The closing date for the receipt of applications, in Australia and London, is August 9, 1958.

EXPERIMENTAL OFFICER

required by

THE ATOMIC WEAPONS RESEARCH ESTABLISHMENT, ALDERMASTON, BERKSHIRE

to be responsible to the Laboratory Manager for the work of a small team engaged on general inorganic chemical analysis.

H.S.C. (Science) or equivalent is minimum qualification, and extensive experience in metallurgical analysis, including the analysis and control of trade waste effluent, is required. Several years' supervisory experience advantageous. Candidates should be at least 26 years of age.

Salary: £990 to £1,215 per annum.

Contributory Superannuation Scheme. A house, or assistance towards legal expenses on house purchase, will be available for married officers living beyond daily travelling distance.

Postcards for application forms to the Senior Recruitment Officer at above address. Please quote ref. A/1736/34.

UNIVERSITY OF EDINBURGH

DEPARTMENT OF BIOCHEMISTRY

Applications are invited for the post of Assistant in the Department of Biochemistry. Salary scale, £700 by £50 to £850 per annum, together with superannuation benefit and family allowance where applicable. Applicants should possess a first- or second-class honours degree in biochemistry or chemistry. The successful applicant will be required to undertake research work in addition to laboratory teaching duties to medical, dental, and veterinary students. The Assistant will be expected to take up duty on October 1, 1958.

Further particulars may be obtained from the undersigned, with whom applications, giving the names of two referees, should be lodged not later than July 26, 1958.

CHARLES H. STEWART,
Secretary to the University.

OXFORD UNIVERSITY

DYSON PERRINS (ORGANIC CHEMISTRY) LABORATORY

POSTDOCTORAL FELLOWSHIPS

Two or more postdoctoral fellowships are available for research on a variety of problems in organic chemistry. Salary at least £700, depending upon age and experience.

Applications, including the name of a referee, to the Administrative Officer, Dyson Perrins Laboratory, South Parks Road, Oxford, before July 19.

UNIVERSITY OF TORONTO

DEPARTMENT OF MATHEMATICS

Applications are invited for positions as Lecturers in Mathematics with duties to begin September 15, 1958. The salary is $5,100 or better per annum depending upon qualifications and experience. The fields of competence preferred are applied mathematics and analysis.

Applications should be addressed to Professor D. B. DeLury, from whom further particulars can be obtained.

UNIVERSITY OF ADELAIDE

AUSTRALIA

WAITE AGRICULTURAL RESEARCH INSTITUTE

Applications are invited for appointment as Biometrician at the Waite Agricultural Research Institute of the University. The appointment will begin not earlier than January 1, 1959, when the post falls vacant by resignation of the present holder. Duties: To assist research workers at the Institute in the design analysis and interpretation of their experimental programmes; to give an introductory course of lectures on biometry in the Faculty of Agricultural Science; to supervise the records of permanent field experiments and meteorological observations. Status and salary: The appointment carries the status and salary of a Senior Lecturer in the University. Salary range: £A.2,100 by £A.80 to £A.2,500. Superannuation: On the F.S.S.U. basis. Terms: A copy of the general conditions of appointment of Senior Lecturers in the University may be had on application to the Registrar of the University or from the Secretary of the Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1. These conditions apply to appointments at the Institute except insofar as academic terms and teaching duties are concerned.

Applications: An application must include particulars of age, nationality, marital status, academic record, experience, war service (if any), and present position; a list of publications; copies of testimonials; the names and addresses of two referees of whom confidential inquiries may be made; a recent photograph; and a medical certificate of good health. It should be lodged, in duplicate, with the Registrar, University of Adelaide, Adelaide, South Australia, not later than August 13, 1958. Further information about the post or about the University and the Waite Institute will be supplied on request to the Registrar.

UNIVERSITY OF SYDNEY

AUSTRALIA

LECTURESHIPS IN PSYCHOLOGY

Applications are invited for two positions of Lecturer in Psychology. The salary for a Lecturer is within the range £A.1,500 by £A.90 to £A.2,100 per annum, plus cost of living adjustment and will be subject to deductions under the State Superannuation Act. The commencing salary will be fixed according to the qualifications and experience of the successful applicant. Under the Staff Members' Housing Scheme, in cases approved by the University and its Bankers, married men may be assisted by loans to purchase a house.

Further particulars and information as to the method of application may be obtained from the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1. The closing date for the receipt of applications, in Australia and London, is August 15, 1958.

INTERNATIONAL RED LOCUST CONTROL Service requires a Scientific Officer for research on population dynamics of the Red Locust in the Rukwa Rift Valley outbreak area in Tanganyika. Objectives: first, to improve methods of enumeration of the locusts, dealing particularly with systematic errors and with problems arising from clumpy distributions and to apply the methods; a knowledge of statistics is therefore advantageous. Second, to study the annual rise and fall of numbers and elucidate quantitatively the factors, biological and physical, affecting numbers. Ultimate objective: to discover new possibilities of ecological prevention of Red Locust plagues to substitute for the present successful but expensive insecticide control. Six other scientists in the Service, of whom three are working in this field. Candidates must be physically sound and capable of original work, with at least a good honours degree, preferably in zoology. The essential common languages are English and Kiswahili; it is not difficult to learn sufficient of the latter. Minimum starting salary £1,035 per annum, then increments as in Oversea Civil Service (Research Branch) in Northern Rhodesia, with promotion prospects to higher grades. Free housing, with 15s. daily bush allowance while working outside Abercorn. Basic furniture provided; outfit allowance £40; tours of duty 20-36 months, with paid home leave at five days per month; air passages provided in full, including wife and children, on appointment and leave. Gratuity 10 per cent of salary for first three years, 15 per cent for second three years, 20 per cent thereafter; alternatively F.S.S.U. (with supplementary gratuity after three years) or O.C.S. pension conditions carried on.—Write to the Crown Agents, 4 Millbank, London, S.W.1. State age, name in block letters, full qualifications and experience and quote M3B/44854/NF.

DIFCO ***microbiological reagents and media***

PEPTONES *and* HYDROLYSATES

for Microbiological Culture Media

Difco peptones and hydrolysates are prepared to meet the diversified nutritional and biochemical requirements of microorganisms. A single peptone cannot provide the essential nitrogenous nutriments for all cultural and metabolic processes. Difco peptones and hydrolysates have been developed to meet the various requirements for microbiological procedures including growth, preparation of toxin and vaccines, and for the study of microbial metabolism.

EXPANSION OF UNIVERSITY EDUCATION IN BRITAIN

THE report on "A Policy of University Expansion", which was adopted by the Council of the Association of University Teachers on December 18, 1957, was only published* in May after the Government had announced a further grant for university building in Britain of £15 million in each of the years 1960–63, and set a target of 124,000 students, with a temporary increase of 10 per cent during the period 1965–70, in place of the 106,000 students previously suggested by the Treasury. In the meantime, however, while the importance of quality in education has received repeated emphasis in various pronouncements on industry and education, and particularly in A. G. Korol's study of Soviet education for science and technology, a series of articles in *Research* on the educational framework of an industrial society have explored further the implications for the universities of the demands of technology. Much attention has also been directed to the question of university awards, and on June 6 the Minister of Education, Mr. Geoffrey Lloyd, announced a new scale of grants for students which, with other changes, will cost nearly £2,000,000 in a full year.

Under the new scales, the parental contribution is decreased while the grants themselves are increased; and the Minister has also approved increases for students at training colleges for technical teachers which implement recommendations of the Willis Jackson Committee on the supply and training of teachers for technical colleges, besides recommending to local education authorities that students more than eighteen years old pursuing degree or equivalent courses at technical colleges and similar institutions in Britain should receive awards at the university rate. He has also again emphasized the importance he attaches to the maintenance of uniformity in grants to university students throughout the country, and hopes that all local education authorities will adopt the new rates for holders of awards in their own areas. While the increases are roughly double those made three years ago, they increase the disparity between grants for those in training colleges and those for holders of university awards, and, from this point of view, may do nothing to ease the critical shortage of teachers. It could be argued that it would be administratively much tidier to abolish the means test altogether and also the tax allowances for children at a university; but nevertheless the new scale of parental contribution represents an honest effort to eliminate, within the limits set by the Education Act, what may be described as the 'second surtax' hitherto levied on the higher paid parents of intelligent children. It will not enable every gifted pupil to accept a university place without imposing real sacrifices on his family, but it should reduce further the risk that purely financial reasons will cause some really gifted individual to forgo the training which would develop his talents to the full. Even if it did no more than ensure for the nation the services of half a dozen such outstanding scientists or technologists, the new scale would be worth while; for what needs to be remembered above all in considering the expansion of university and technological education is the importance, not of seeing that every potential student of marginal ability has a university place, but of ensuring that no boy or girl of really outstanding ability misses one.

We seem, in fact, to be in some danger of expanding university and technological education too much in the former direction. There are limits, as the Chancellor of the Exchequer quite rightly said in the House of Commons, to what Britain can spend even on university education, and it is at least debatable whether the type of university education which the really gifted should receive is exactly that which is best suited to the average university student. We may be attempting to provide many students with a much more expensive type of education than they need and one from which they are unlikely to profit fully.

This may be represented as an attempt to lower university standards, but it indicates the type of question about the nature and purpose of a university education which should be asked in considering the report of the Association of University Teachers and such statements as that of the Labour Party on "Learning to Live". They are no less relevant in discussing particular aspects of university education, such as the founding of Churchill College at Cambridge and the recent statement on university awards, and appear largely to have been ignored by the National Union of Students in its comments on the new scale, though many of the changes are welcomed.

The Association of University Teachers begins with a general discussion of the nature of university education, in which the unique nature of the universities as institutions for both the advancement and the dissemination of knowledge is rightly stressed. The special value of a university education is based mainly on the way in which it brings the student in personal contact with those who are advancing knowledge; on its unhurried character, in which acquisition of the art of learning takes precedence over acquisition of factual knowledge; and on the varied types of student and scholar and the branches of learning with which the student is brought into contact. All these features of a good university education could be destroyed if student numbers so increased in relation to the number of teachers as to make research difficult and personal knowledge of individual students impossible, or by attempts to produce excessive numbers of fully trained specialists.

---

* Association of University Teachers. Report on a Policy for University Expansion. Pp. 14. (London: Association of University Teachers, 1958.) 3s.

This is rightly represented by the Association, irrespective of whether its views as to the practicability of sufficiently increasing the number of university teachers or on the conditions necessary to recruit and retain them are sound. What needs to be emphasized is that it should not be assumed that the student himself is necessarily to advance knowledge. Excessive emphasis on research may increase the cost of a university education, fail to develop many students according to their innate abilities and provide too many graduates of a type and outlook which industry finds unsuitable.

In this connexion, observations on residence and on the size of a university are pertinent, and the paper which Sir Keith Murray read to the Royal Statistical Society on May 14 is of special interest. The Association, stressing the importance of a sufficient leavening of senior members of a university, endorses the view that a university hall of residence should have some 150 students, and it is convinced that new halls of residence are essential to any scheme for a substantial increase in the number of students. Sir Keith Murray is concerned not simply with the possibility that the universities of Britain may become too large to serve the national purpose, but with the effect of the current tendency on the work of the universities themselves—whether we might do better to spend the same amount of money on fewer people, as Lord Woolton recently speculated at Founders' Day in Manchester.

During 1955–56, Sir Keith observed, excluding Oxford, Cambridge and London, sixteen university institutions, containing 35·2 per cent of the students, had less than 2,000 students. By the late 1960's, only four institutions, containing 9·2 per cent of the students, are expected to contain less than 2,000 students, and more than half the university students will be in institutions of more than 5,000. The Government's university building programme already mentioned visualizes an increase of 50,000 students on 1955 by the mid-1960's, and Sir Keith is seriously concerned as to the possibility in such conditions of maintaining the three ancillary freedoms on which the maintenance of freedom of thought depends. That freedom does not require simply freedom from any form of political intervention; it may also be prejudiced by failure to maintain the freedom of a university to make its own appointments to teaching posts, and freedom from external control over either what is taught or admissions.

The universities therefore should not be content to consider expansion mainly in terms of the availability of students of appropriate intelligence quotient. On that basis the Association of University Teachers estimates that the schools could increase the number of pupils taking two subjects in the General Certificate of Education at advanced level by 55 per cent on the figures for 1954, and that the university intake could increase correspondingly. It also estimates that the proportion of the population with high enough intelligence quotient to meet present university entrance requirements is 6·9 per cent compared with the 3·2 per cent who reached the universities in 1954. Even 95 per cent of these would require 145,000 university places by 1965—some 10,000 more than the maximum provided for in the Government's revised plans announced last February.

This, however, is the target which the Association of University Teachers accepts. It suggests that the university population should increase by 35 per cent on 1956–57 by the academic year 1962–63, and by 63 per cent from 1966–67 onwards. Non-collegiate universities should not be encouraged to expand beyond 4,500 students—in other words, to more than double their size—in ten years. This policy would provide a maximum of 23,000 fewer places than the target figure, and the Association suggests accordingly the founding of new universities so that they can make a significant contribution during the period 1961–66. These universities, which should be largely residential, should give their own degrees, initially under the sponsorship of some existing universities. Sites mentioned in the report are Norwich, York and Leamington and, because of the location of many research associations there, Leatherhead. In technology, the Association recommends the use of postgraduate courses to train academically qualified graduates for specialized professional employment.

Even if the assumption that university places should necessarily be available for all school leavers of high enough intelligence quotient to meet existing university entrance requirements is unchallenged—and this ignores the claims of both the colleges of technology and the technical colleges and presupposes that a university education is the most desirable means of training men and women for leadership and responsibility in any sphere of life—targets of that magnitude are best justified on practical rather than theoretical grounds. Sir Solly Zuckerman has recently examined, in the *Universities Quarterly* of May, the implications of the policy of technical education in Britain outlined in the White Paper of 1956, and of the latest proposals for university expansion to provide the estimated necessary output of professional scientists and engineers which would be needed by 1970. During the next ten to fifteen years that report suggested we should aim at an annual output of about 20,000 professional engineers and scientists compared with 10,000 at the time of the inquiry.

If the technical colleges succeed in implementing the White Paper policy, Sir Solly Zuckerman estimates that by 1965 they could supply about 9,500 professional scientists and engineers, including 1,000 with external university degrees. This would rise to about 10,500 by 1970. By the end of the 1960's the university output should rise to 11,000, including 1,500 qualified in special technologies, or 4,500 a year more than in 1955–56. The increase in university places provided in the February 1958 statement should be sufficient to enable the universities to play their part in doubling the present output of scientists and engineers in Britain, and with 20,000 places for students of medicine, dentistry, agriculture and veterinary science would still leave 50,000 places for the humanities compared with 37,000 in 1955–56.

Sir Solly points out, however, that all this depends on the ability of the schools to supply the entrants. The technical colleges, for example, will require an input of 23,000 by 1967–68, and for the current academic year entries in science and technology are 10,800 compared with 7,300 in 1953. A university population of 124,000 implies an annual entry of 35,000, of whom 2,500 would be from overseas, and the 10 per cent increase would raise this to 38,000 in the late 'sixties. Allowing about half the technical college entry to be from school sixth forms, with some 10,500 for teachers' training colleges, it will be seen that in 1967–68 some 53,000–56,000 from the schools will be required for academic education out of an intake of 64,000–67,000, compared with 37,000 in 1955–56.

Figures like these put the question of teachers in its right perspective, and especially the critical importance of science teachers. If the plans already laid are, in fact, to meet the nation's requirements, their implementation must proceed smoothly and unhindered either by critical shortages or by delays. The Association of University Teachers regards the availability of staff as the most probable limiting factor in the expansion of university education in Britain, and is dubious as to the ability of the universities to recruit a sufficient proportion of first-class honours graduates. It may well be necessary to increase the present proportion of 41 per cent of second-class honours men on university staffs; but the position is one that calls for even greater attention to the efficient use of university staff. The provision of auxiliary staff, known to be comparatively low in universities compared with elsewhere, may be a most important factor in maintaining university standards with a smaller number of highly qualified staff. It is, however, no less important that the needs of further or higher education for those not up to the level of two passes at advanced level of the General Certificate of Education should not be overlooked. As the report on "Early Leaving" indicated, there is here a most important source of the technicians and auxiliary staff on which the most efficient use of the more highly trained scientist, technologist or administrator depends.

The Association of University Teachers cannot fairly be charged with timidity in its approach to university expansion, though it could well be regarded as questioning the soundness of the ultimate target of at least 160,000 places advocated in the Labour Party's statement, "Learning to Live". Nevertheless, in its reference to the universities and to technical and scientific education that statement is reasonable, though the pertinent questions raised about the universities, such as their size, distribution and finance, should, it is suggested, be referred to a royal commission. That suggestion, however, is not without value, and though it seems to lack the urgency needed it could provide some of the safeguards which would encourage constructive response by the universities themselves. There is genuine concern in university circles that a university may cease to be a university if expansion proceeds without due regard to the importance of adequate library facilities, the ratio of staff to students and the balance between different faculties.

No one who studies the annual returns published by the University Grants Committee would suggest that fears on such points are unreasonable. The Association of University Teachers could well have put the case for library expansion much more strongly, for the returns indicate little proportionate attention to the expansion of university library facilities in the post-war years. This, however, is only one illustration of the need for a marked improvement in the real resources of universities, to enable them to make experiments in the curriculum and the varieties of degrees offered, and it is not too much to urge that the higher the proportion of the population entering the universities, the more essential it is that experiments should be made and variety offered.

Prof. Asa Briggs has argued very reasonably in the *National and English Review* for greater differentiation between the universities. The provincial universities should not seek to imitate Oxford and Cambridge, but emphasize and develop their own distinctive advantages. Diversity already exists between the provincial universities, but more is possible, and the greater academic mobility which, as Prof. Briggs points out, is also needed, could assist.

What are needed here—and indeed at all stages in concerting a policy of university or technological or technical education—are vision and judgment, in order to avoid dissipation of resources on secondary objectives and the loss of the full effect of sound measures for lack of essential support at some stage or other. There is substance in the argument, for example, that even the creation of a new college, such as Churchill College, except as part of a considered university policy, could prejudice decisions on vital national questions such as the proper size of Oxford and Cambridge, the location and character of a third residential university, and whether a major new college of technology should be located near some great centre of industry. Without vision, too, doctrinaire considerations may affect adversely critical factors like academic autonomy and the co-operation which is essential from many varied interests and sectors in the national life.

The report of the Association of University Teachers touches on several of these important issues, but by no means all. Sir Solly Zuckerman indicates more clearly how university expansion depends critically upon educational policy in the schools, but even this pragmatic approach by itself is not enough. The continuing need is for independent, uninhibited and constructive thinking about the nature and purpose of university education and their relevance alike to the needs, aspirations and capacities of both students and teachers, and to the needs of the society in which universities exist. Another major consideration is the magnitude of the resources which society can place—and is willing to place—at the disposal of universities, colleges of technology, technical colleges and the schools.

GEOGRAPHICAL DISTRIBUTION OF ANIMALS

Zoogeography

The Geographical Distribution of Animals. By Dr. Philip J. Darlington, Jr. Pp. xi+675. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1957.) 120*s*. net.

The Faunal Connections between Europe and North America

By Carl H. Lindroth. Pp. 344. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd.; Stockholm: Almqvist and Wiksell, 1957.) 120*s*. net.

THESE two books are both written by experienced taxonomists with special knowledge of the Carabid beetles but much wider interests as well, and both are stamped with the care and integrity of good museum research, backed with a great deal of collecting in various places. Since the publication of A. R. Wallace's classical book on "The Geographical Distribution of Animals" in 1876, there has been no general handbook of zoogeography giving reliable detailed facts about distributions for the whole world, and a balanced, critical assessment of their origins. There have been plenty of interesting essays as well as a lot of very unreliable speculative books and papers, many good regional surveys, studies of island groups or of ancient lakes—a mounting pile of unrelated facts and theories; but nothing one could use for a general interpretation of present distributions and faunal history.

Dr. P. J. Darlington's book goes a very long way towards providing an authentic review of our knowledge of the distribution of vertebrates (to which his analysis is confined), and some way toward fitting them into faunal history. But most of his text is a solid concrete-mix of facts and very closely woven comments upon them, only seventy pages being devoted to a general statement of his views on faunal history as a whole. About a quarter of the book is actually composed of tables summarizing the present and fossil distribution of each family of vertebrates, that is, of the freshwater and terrestrial ones. These are the result of twenty years very careful compilation and checking, and are presented in a thoughtful and critical manner, though in such complex detail that reading is not easy. But any zoologist who enjoys browsing in dictionaries can only emerge from reading this material with an enriched realization of the complexity and interest of zoogeography.

The text has a number of maps, though no list of them is included. The world maps are on an orthographic projection, so that two overlapping maps are needed for a whole world distribution. The author objects to Mercator's projection as misleading; but even though it is a scale convention, I think it much more convenient to look at the world in one piece. The ability of animals to spread quite quickly in the absence of barriers is stressed by the author himself, and this seems to make differences of relative map scale fairly unimportant. He uses wide gridiron markings to show distribution areas, presumably to avoid a misleading appearance of precision in mapping ranges. These make the world look as if it has suffered injuries and been covered with sticking plaster—a convention already suitable to conservation, and perhaps soon also to natural zoogeography.

Dr. Darlington has a highly personal style, his text is laced with decisive opinions, but most of his conclusions seem sound, though perhaps rather conventional. One feels that if a new and daring idea were to be put forward (for example, by another Wegener) he might quickly reply: "But do you realize that didelphids died out temporarily in North America in the Upper Miocene", or some such hard fact—and that in many instances he would probably be right. But many of his opinions cannot be proved, for that is the curse of so much in zoogeography, where the final answers to many of the largest questions must await the further discovery of relevant fossils. One general criticism can be made of the book (which is so genuinely learned and anxious to state conclusions fairly), apart from its lack of ecological ideas. We know that of the great groups of animals like freshwater fish, birds and mammals, that underwent rapid evolution during the Tertiary isolation of continents, good fossil history is available only for some mammals. Most terrestrial and freshwater groups had already evolved far towards a final stage before these continental isolations arose. What we see now is a complicated mosaic of earlier wide distributions now contracted or broken in bits; regional ones attributable to Wallace's 'realms'; redistributions from about the Pliocene onwards; and later blurrings caused by man. For the explanation of most of these patterns we depend on complicated cross-arguments (this book abounds in cross-references) unsupported by a fossil record. This is why a work that concentrates on describing the modern distributions of vertebrates can only include a small amount of proved faunal history to go with it. But zoologists will for many years seek some of their basic facts here, and find them discussed in honest and sensible terms. They will also encounter some ideas that may be new to them, such as the ancient Central American sub-continent that is postulated, and the notion that Madagascar, like New Zealand, may never have been joined to any mainland mass.

Dr. C. H. Lindroth has written a special monograph rather than a book for general reading. It is in three almost equal parts. The first is a detailed tabulation of the present distribution of about 900 species of animals common to Europe and North America, though many of them range much wider, especially into Asia. They include mammals, birds and fish, and a selection of insects, spiders, myriapods, land isopods, molluscs and worms. The list is not claimed to be anywhere near complete, because the author has sensibly chosen groups of species the taxonomy and distribution of which are likely to be reliably known. About 45 per cent of these species include introductions by man. The second part of the book is an analysis of introduced forms, especially those taken accidentally in the ballast of shipping, with some personal surveys of ballast ground-faunas both in Britain and Newfoundland, and a historical survey of earlier shipping trends. It is concluded that introductions by this and other means have been about ten times more common from Europe to North America than in the other direction. The third is the least satisfactory part of an interesting and original monograph, as it discusses in a manner which is rather too condensed a great many controversial questions of faunal history before the influence of man began. Nevertheless, the author has brought out the rather small common element in the native faunas (at any rate at the species-level) on opposite sides of the Atlantic, and the growing force of invasions made possible by shipping in modern times. There are some good maps, but the book could have been more cheaply printed without loss of usefulness and with more likelihood of being read by students.

CHARLES S. ELTON

EUROPEAN ORTHOPTERA

Die Geradflügler Mitteleuropas

Von Kurt Harz. Pp. xxiii + 494 + 20 plates. (Jena: Gustav Fischer Verlag, 1957.) 69.20 D.M.

THERE has been no book on the Central European Orthoptera since 1901, when the first edition of Tümpel's brief, and now quite out of date, "Die Geradflügler Mitteleuropas", was published. Indeed, with the exception of France, no single country in Europe has its grasshopper fauna covered at all comprehensively, even at the present time. Kurt Harz's book has thus been presented to an entomological public which conspicuously lacks an authoritative work on the Orthoptera of Central Europe. It is true that our knowledge of such aspects as the biology and distribution of European grasshoppers is still little better than rudimentary, but this must be due in no small way to the absence of a publication presenting an up-to-date picture of what facts have so far been established.

The area covered by this book extends east to west from the Rhine valley to the Carpathians, and north to south from the north coast of Germany to the Alps. More strictly, the author regards the following countries as being in Central Europe: Germany, Switzerland, Liechtenstein, Austria, Poland, Czechoslovakia, Hungary, and Roumania. The author, however, recognizes that the Central European fauna has little respect for political boundaries, and he does not therefore exclude Belgium, Holland, Luxembourg, and a strip of northern France. In his introduction, he makes the interesting point that, of the 200 species of his group which occur in the area thus delimited, only 45 occur in Hungary or Roumania or south of the Alps.

Included under the heading "Geradflügler" are the Orthoptera in the widest sense, and the Dermaptera. Following the modern trend, the Blattodea, Mantodea, and Saltatoria are treated as separate orders. Also conforming to recent practice, though less justifiably, many of the groups generally regarded as subfamilies have been given family status.

The arrangement of the book is very systematic and makes for great ease of reference. Even very minor subdivisions of the subject-matter, some occupying no more than two or three lines of print, are given separate sub-headings, and all these, very commendably, are listed in the contents—which occupies a dozen pages. Under each order there is first a general account of the morphology, anatomy, physiology, embryology, and behaviour of the insects included; notes on capture and preservation are also given. Although the information on many of these topics is very brief, the wide coverage of the subject-matter is commendable and greatly increases the value of the book.

Identification keys are given at every level of the classification. A certain amount of ease in identification must therefore have been sacrificed in order to show the natural relationships of the members of each group. For example, the user is obliged to make a critical examination of the subfamily characters (frequently microscopical and often difficult to appreciate) in order to identify a species which may have obvious spot characters.

Under each species the author gives a brief description and notes on the biology of the insect. For the Saltatoria quite comprehensive accounts are also given of the various types of stridulation of each species. The treatment of each insect concludes with a fairly detailed account of its distribution.

The book is profusely illustrated: there are 255 text-figures (including a number of photographs) and 20 colour-plates. Many of the text-figures are redrawn from previously published works but a large proportion is original. These, the photographs, and the colour-plates, are all apparently the work of the author. The standard of the drawings in the text is poor; the intention, evidently, was not to present a high degree of accuracy or to give the illustrations artistic finesse. Difficult points which arise in the identification keys are, however, adequately figured, and a drawing of the whole insect is given for almost every species. The colour-plates are again not of the highest quality, but nevertheless form a most useful supplement to the text-figures. Pictures of some of the different colour-varieties of a few species of Acrididae are wisely included among these plates.

The book concludes with a short glossary of technical terms, a list of abbreviations of authors' names, a comprehensive bibliography including some 500 titles, and indexes to both German vernacular names and Latin names of taxonomic categories.

It should be emphasized that this book is not written for the casual nature lover and is too advanced for even the most ardent schoolboy enthusiast. It is rather aimed at serious naturalists and specialists in entomology, and is sufficiently authoritative and comprehensive to be quite indispensable to any keen student of European Orthoptera. The author has clearly devoted many years to the study of his subject and the literature relating to it; his object in writing the book—to present an up-to-date basis for further studies and to show where the biggest gaps in our knowledge lie—will surely be realized.

DAVID R. RAGGE

MICRO-ORGANISMS IN MILK AND MILK PRODUCTS

Dairy Microbiology

By Prof. Edwin M. Foster, Prof. F. Eugene Nelson, Prof. Marvin L. Speck, Prof. Raymond N. Doetsch, and Prof. Joseph C. Olson, Jr. Pp. xvi + 492. (Englewood Cliffs, N.J.: Prentice-Hall, Inc., 1957.) 5.65 dollars.

THERE are few books on dairy microbiology and their usual pattern is a description of microbial defects in milk or milk products, the naming of the causal organisms and suggested measures for control. The authors of "Dairy Microbiology" attempt first to provide for the reader a foundation of basic information on microbes of importance in the dairy industry, which will enable him not only to have a little insight to taxonomy, but also to appreciate why specific defects may occur. Before these defects are considered the reader is given a short course (or refresher, as the case may be) on the control of the growth of micro-organisms, their destruction by physical and chemical agents, and the various methods used to examine dairy products for micro-organisms. In the introduction the concept of the speed with which micro-organisms can bring about changes in milk is vividly presented by a discussion of the ratio of cell volume to surface area. A quart of milk soured by *Streptococcus lactis* contains about 10^{12} cells which would present an enzymatically active surface of about 50 square feet.

A small weakness of the book is the rigid insistence on the logarithmic order of death. While such a conception is convenient for the purpose of calculation, this aspect could have been maintained by the statement that for most purposes the speed of reaction was so great that the sigmoid nature of time-death curves could not be determined, and that they appeared to be logarithmic. This would prevent the discriminating reader from puzzling over the reason why one class of biological life should differ from all the rest in that the cells were all of uniform resistance.

It is, of course, relatively easy to make criticisms of any text-book dealing with a wide subject. The applied aspects cover the microbiology of milk on the producing farm, of market milk and related products, of condensed, concentrated and evaporated milk, of ice cream, fermented milks, cheese, cream, butter and waste products.

This book suffers from the defect we have come to regard as usual in American work: insufficient reference is made to European work.

The book is well indexed and illustrated. A 'modern touch' is given to the book by the fact that the illustrations are frequently carried over the margin to the edge of the page. In some cases this allows a saving of space and the reproduction of a larger picture.

While this book is written mainly from the American point of view, a great deal of what it contains is of use to dairy technologists in other continents.

L. F. L. Clegg

ROYAL JELLY

La Gelée Royale des Abeilles

Son Histoire et ses Propriétés, sa Composition—ses Utilisations en Diététique et Thérapeutique Humaines. Par B. de Belvefer. Pp. 470. (Paris: Librairie Maloine; London: Apiserum (James Lowe), 1958.) 4,000 francs; 84*s*.

This volume starts with a famous quotation by Pasteur, pointing to the distinction between science and its applications. Unfortunately the material in the book is so arranged that it presents the development of our considerable and diverse knowledge concerning bees just as a prelude to the benefits which, in the author's view, humanity will reap from the uses of royal jelly in various medical fields, such as geriatrics and dermatology. This appears to me to be neither science nor application, but misguided enthusiasm.

The principal merits of the book are that in it are assembled the findings of a great number of workers on the subject in many countries and in various branches of science and medicine; and that interspersed in the French text there are numerous summaries in English, German and Spanish, which—though not linguistic masterpieces—nevertheless greatly facilitate its perusal.

The royal jelly—named by François Huber, the famous blind entomologist—is a secretion of the pharyngeal glands of nursing bees; it is the sole food of queen larvæ and, for about three days, of worker and drone larvæ. It is now widely held that the development of sexuality and the longevity of bee queens is almost entirely due to the continued supply of royal jelly during their larval life; and on this assumption was based the expectation that human sexual drive, vigour, longevity and other positive aspects of health might be improved by the oral use of royal jelly or preparations made from it. In the author's view some of these hopes are justified. The great number of chemical analyses, biological assays and clinical reports contained in the book have, however, not convinced me that royal jelly is a particularly potent drug or that it has any unique therapeutic properties; and in spite of various ingenious hypotheses, the most I would say is that according to the data presented its uses can be described as harmless or slightly beneficial if presumably expensive.

On the other hand, it is legitimate to analyse 'bee milk' in its own right and to study the part it plays in the determination of caste and in the social life of honey bees in general; and for this the book provides much valuable information. One serious mistake on p. 331 is that Butler's queen substance is erroneously identified with the royal jelly. Also it is difficult to understand why von Frisch's experiments on polarized light and on bee language are described in Chapter 6, entitled, "Sécrétion de la Gelée royale". There is no index.

H. Kalmus

DEVELOPMENT OF SCIENCE

Histoire de la science

Publié sous la direction de Maurice Daumas. (Encyclopédie de la Pléiade.) Pp. xlviii + 1904. (Paris: Gallimard, 1957.) n.p.

This pocket-sized volume, the fifth in the "Encyclopédie de la Pléiade", is designed to constitute a complete synopsis of the historical development of the sciences from their earliest beginnings up to the most recent speculations. It has been prepared under the direction of a distinguished French scholar, M. Maurice Daumas, who, in a thoughtful preface, traces through the centuries the gradual establishment of the history of science as a recognized discipline and discusses the present organization of the subject. Confronted by the growing popular distrust of the scientist and by the competition between humane and technological ideals, he would centre education upon the theme of science conceived as a purposive human activity unfolding itself in history.

In the first of the main articles, M. Daumas follows through the ages the varying fortunes of the typical man of science—his status in society, the economic basis of his activities, and his developing techniques of investigation and communication. The next section, which deals with ancient and medieval science in all its aspects, is from the pen of the late Pierre Brunet, while Robert Lenoble, the biographer of Mersenne, analyses the vicissitudes of scientific thought in the sixteenth and seventeenth centuries. He deems the modern age to have begun with the earliest conception of a 'mathematical physics' such as Bacon never anticipated but which found full expression in the work of Galileo, the seventeenth-century advances in the techniques of experiment and calculation being motivated by, and not antecedent to, the scientific revolution.

Thereafter the several branches of science, as conventionally distinguished, are separately followed along their parallel lines of development from the sixteenth century to our own day—mathematics by the late Pierre Humbert and René Taton, astronomy by Humbert and Evry Schatzman, physics and chemistry by Maurice Daumas and Rodolphe Viallard, mineralogy and geology by Arthur Birembaut, geography by Antoine Bonifacio, the biological sciences by Maurice Caullery, and the human sciences (comprising anthropology, ethnography, sociology, demography and psychology) by Paul Lester, Paulette Marquer, Alfred Sauvy, Lucien Daumas, François Le Terrier and Gilbert Simondon.

The immense scope of the work has been attained at the cost of a severe condensation of the material, and there is no detailed documentation, although most of the sections are provided with bibliographies. The book is primarily intended to serve as a work of reference; but it should also afford the general reader a useful guide to the intricate pathways by which the sciences have attained their present levels of development.

Errors have not been entirely eliminated from the text. Joseph Priestley becomes "John Priestley" in the introduction (p. xv) although not in the body of the work; and the Doppler displacement suffered by a spectral line in consequence of the recession of the luminous source from the observer should be towards the red and not the violet end of the spectrum (p. 792). A. Armitage

PARAPSYCHOLOGY TO-DAY

Parapsychology

Frontier Science of the Mind—a Survey of the Field, the Methods, and the Facts of ESP and PK Research. By Prof. J. B. Rhine and J. G. Pratt. Pp. ix+220. (Oxford: Blackwell Scientific Publications; Springfield, Ill.: Charles C. Thomas.) 37*s*. 6*d*. net.

This book is by far the most convenient and well-designed summary of the present state of one branch of parapsychology that has yet appeared. The authors believe that the reality of extra-sensory perception (ESP) and psychokinesis (PK) is now fully established and that therefore it is time to take a general survey of the whole subject, indicating where progress has been made in the past and where it is likely to be made in the future.

The book is divided into two parts. In the first section an account is given of the facts as the authors see them and the main problems are discussed. Telepathy and clairvoyance are dealt with, and the case for psychokinesis concisely summarized. General research on extra-sensory perception is then related to that in other subjects, such as anthropology, psychology and psychiatry.

In the second part the most customary testing techniques are clearly described and the commonest statistical methods briefly outlined. The book closes with a few statistical tables, a glossary of terms and indexes to both names and subjects.

As indicated in the foreword, the plan of the book is to state the facts and in the list of authorities to refer to those publications where further information is to be sought. In the opinion of the authors the time has passed when the facts can be challenged except on the somewhat extravagant assumption of what would amount to a widespread fraudulent conspiracy on the part of the investigators themselves. A rational consistency in the expanding knowledge of extra-sensory perception is becoming more and more apparent and, as this increases, what was formerly regarded as something so extraordinary as to be beyond belief tends to become more acceptable because it is more familiar. The authors insist that the phenomena are to be seen as a means of interaction between a person and his universe or, in other words, a method of subject–object interaction. The main difference between this functioning and that on which our ordinary subject–object relations through the sensorimotor system depend, is that the operation is non-physical, although to be objectively manifested it must be converted into observable physical effect. For example, in extra-sensory perception the information acquired must be converted into some conscious experience such as a dream, intuition or hallucination.

On looking back over the past twenty-five years and then consulting this book, the reader can scarcely fail to be struck by the progress that has been made. If new to the subject, he would never imagine that many of the admirable precautions herein described have only been adopted and accepted after long and bitter controversy. Indeed, it is somewhat to be regretted that the authors have seen fit to omit in their references for further reading so many of the important papers which have been published criticizing the methods and experiments of the parapsychologists, since it can scarcely be denied that to some of these critics are due the improvements in technique that have been made.

Although the authors have been mainly concerned with the evidence for and investigation of the phenomena of extra-sensory perception and psychokinesis as seen in action with human beings, they have in more than one place suggested that the phenomena of homing, migration, etc., might be more fully understood if it were recognized that extra-sensory perception occurs and might be relevant. In this connexion they point to the cases in which, it is alleged, some domestic animal, left behind by its owners in its old home, later follows them to their new location, sometimes hundreds of miles away, where it has never been before. Certainly such a case, if properly authenticated, would provide a puzzle to any zoological student; but it is interesting to note that not a single reference is given to any fully described and documented occurrence of this kind.

Apart from occasional examples of this sort, where enthusiasm has perhaps been allowed to overstep its boundaries, the book shows a moderate and restrained attitude which is to be welcomed. As a stimulating account of work in a new and extremely complex field it can be recommended to anybody who thinks of beginning experimental work on extra-sensory perception and similar phenomena.

E. J. Dingwall

Atomic Energy in Agriculture

By William E. Dick. (The Atoms for Peace Series.) Pp. x+150+16 plates. (London: Butterworths Scientific Publications, 1957.) 15*s*.

THE title of this small book suggests an enormous field and it is fair to say that it deals with only some aspects of this, comprising almost entirely biological applications. The book is mainly a collection of notes (to which explanatory texts have been added to provide the background) of papers relevant to agriculture presented at the International Conference on the Peaceful Uses of Atomic Energy held in Geneva in 1955. It would have been of considerable assistance to the prospective buyer if this had been indicated in the title.

The largest and the most interesting chapter is on radiation genetics, which consists almost entirely of accounts of Swedish experiments and of work in the United States. The chapter on photosynthesis, although brief, shares with those on pests and forestry the distinction of being nearly as interesting as the one on radiation genetics. The isotopes oxygen-18 and carbon-14 play the principal parts in this account in elucidating (*a*) the origin of the oxygen evolved during photosynthesis, (*b*) the nature of the primary product of photosynthesis and (*c*) the metabolism of carbon dioxide through the roots. In dealing with pests, the book describes radiotracer studies on the physiology, movement and ecology of insects and animals as well as the metabolism of insecticides by insects. One rather novel use of X-rays from cobalt-60 in pest genetics is described—to produce sterile male flies of the screw-worm—which eventually eradicated this pest from the island of Curaçao. The section on forestry describes the use of bromine-82 at Wisconsin to reveal the existence of root grafts in colonies of trees. The grafts enable nutrient ions to pass from vigorous trees to weaker ones and also allows spores of fungus diseases labelled with silver-110 and iodine-131 to pass from tree to tree. The last chapter deals with the economics and technicalities of food preservation by atomic radiation and gives the reader a good idea of the problems for research which arise out of an apparently simple project. The account of work on 'other elements' attempts to deal with a vast field in a comparatively short space and fails to do full justice, except perhaps in the section on foliar application of fertilizers.

The book is well illustrated and moderately priced. Detectable errors are few; "phosphorus-35" is an obvious printer's error (p. 80) but "millicuries" instead of micro-curies (p. 68 and p. 77) are rather unforgivable slips. A bibliography of all the work referred to would have been much more useful to the reader than the rather pointless index in a book of this kind.

A Monograph on the Termitophilous Staphylinidae (Coleoptera)

By Prof. Charles H. Seevers. (Fieldiana: Zoology, Vol. 40.) Pp. 334. (Chicago, Ill.: Chicago Natural History Museum, 1957.) 6.50 dollars.

AS a systematic monograph this work is unusual in that it is concerned with an ecological unit. It comprises revisions of those groups of Staphylinid beetles which are obligatory inhabitants of termite societies. The Staphylinidae include not less than 25,000 species, mostly predators, but among them are about 300 species which live only in termite colonies. During the long evolutionary history of termites their colonies have been continually invaded by predators, including Staphylinidae, but the chance of any Staphylinid species so adapting itself to the exacting conditions of the termite society as to become established as a permanent inhabitant is very small. It is of interest, therefore, to learn that the present study of the termitophilous Staphylinidae undertaken by Prof. Seevers indicates that the present fauna of some 300 species has arisen from about six pioneer species. From each of the original successfully established species has arisen a natural group (subfamily or tribe) of termitophile species.

The rarity with which termitophile lines have been established finds a parallel in the origin of the insect fauna of remote oceanic islands. It has been pointed out by E. C. Zimmerman that in the Hawaiian Islands, for example, the present-day beetle fauna of 1,290 species is the result of the establishment of only 40 original immigrant species.

The systematic revision of the termitophilous groups, which occupies the greater part of the work, is dealt with in a thoroughly competent manner. The value of the work is enhanced by the fact that the author had available the finest collection of termitophiles in existence, that of Dr. A. E. Emerson, and was able to study all the important type material. It is perhaps to be regretted that there are few illustrations and that photographs have been used in place of line drawings. The author, however, admits this shortcoming and refers the reader to the many previously published figures. E. B. BRITTON

Introduction to Protein Chemistry

By Prof. Sidney W. Fox and Prof. Joseph F. Foster. Pp. viii+459. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1957.) 76*s*. net.

TO many readers the most valuable and interesting feature of this book will be the inclusion in one volume of an outline of the new and improved techniques for the investigation of the composition and structure of proteins and of the results obtained by their application to insulin and to a number of peptides such as gramicidin, tyrocidine, oxytocin and vasopressin. For the rest, the text largely follows the standard arrangement adopted in works on proteins. An innovation is, however, made by including a chapter on the metabolism of the amino-acids and another on enzymes. This is, in my view, a mistake. The proper setting for such subjects is in a text-book on general biochemistry, where they can be, and generally are, treated much more satisfactorily. The space devoted to a descriptive account of particular proteins and protein systems is quite inadequate. Out of a total of 459 pages only 60, of which 24 deal with the blood proteins, are employed for this purpose and of these at least two are occupied with photographs which have no instructional value. In contrast to this, no fewer than 174 pages are devoted to amino-acids and peptides. It is not, therefore, surprising that there is no proper account of the nature of many proteins such as the glycoproteins and lipoproteins; no reference to the phosphoproteins of the yolks of bird or fish eggs despite the statement that the "principal, if not sole, function" of ovalbumin is the nutrition of the young animal; and no mention of histones apart from the unexplained statement that globins "are classified as histones". E. STEDMAN

NEW ACADEMIC PRESS BOOKS

THE BIOLOGY OF HAIR GROWTH

Proceedings of the International Conference on the Biology of the Hair Follicle and the Growth of Hair held in London under the Auspices of the British Society for Research on Ageing

Edited by WILLIAM MONTAGNA and RICHARD A. ELLIS

Department of Biology, Brown University, Providence, Rhode Island

September 1958, about 525 pp., illus., 100s.

CONTENTS:

LEAK DETECTION

. . . it's elementary

When a Vacuum system begins to leak,
And is out of action for more than a week,
Don't waste a skilled technician's time
With elaborate instruments, trying to find the LEAK

Invest in LEYBOLD detection equipment,
It's safe, it's sure—a sound investment;
And yet another important feature
The total cost is so much cheaper
£160 complete

For further information regarding Leybold Vacuum Leak Detection equipment, please send your inquiries to . . .

There Is a
Delicate Balance . . .
between QUALITY
and ECONOMY

NUTRITIONAL BIOCHEMICALS CORPORATION always assures you the economy of lowest possible prices . . . yet never sacrifices their proudest asset — quality of product.

- OVER 225 AMINO ACIDS
- OVER 90 PEPTIDES
- OVER 200 NUCLEOPROTEINS, PURINES, PYRIMIDINES
- MISCELLANEOUS BIOCHEMICALS
- VITAMINS
- ENZYMES
- GROWTH FACTORS
- STEROID HORMONES
- BIOLOGICAL SALT MIXTURES
- BIOLOGICAL TEST MATERIALS

Three days after your order is received it will be delivered in most parts of Europe.

AUSTRALIAN COMMONWEALTH DEPARTMENT OF SUPPLY: WEAPONS RESEARCH ESTABLISHMENT*

THE Australian Commonwealth Department of Supply is responsible for conducting scientific research and development in relation to war material for the Commonwealth Government in the same way as the Ministry of Supply for the United Kingdom Government. This function is performed by the Research and Development Branch of the Department of Supply, headed by the Department's Chief Scientist. The Branch operates three research establishments, two of which, the Defence Standards Laboratories and the Aeronautical Research Laboratories, are located in Melbourne, Victoria, and the third, the Weapons Research Establishment, has its headquarters located at Salisbury, near Adelaide (Fig. 1), and operates the guided weapons trials ranges at Woomera. Collectively, the staff of these laboratories, together with the headquarters scientific staff, constitute the Australian Defence Scientific Service.

The Weapons Research Establishment, formerly known as the Long Range Weapons Establishment, was instituted by the Australian Government in collaboration with the British Government. In 1946 the British Ministry of Supply considered the possibilities of a number of sites within the British Commonwealth where a range might be established with adequate supporting facilities for testing guided weapons. The requirements included a range upward of a thousand miles long, over reasonably accessible terrain, without danger to established populations, and with adequate assurance of security. In addition, supporting laboratories and workshops and associated industry were required to be available on a substantial scale. Of the various countries considered, Australia appeared the most promising, and this was confirmed by the report of an exploratory party which the Ministry of Supply sent to Australia in the same year.

In the subsequent agreement between the two Governments, Australia undertook to finance, build and operate the range system now established at Woomera and to set up at Salisbury, some three hundred miles to the south, a centre from which the work could be directed, with adequate laboratories and other scientific and technical support for the range activities. Great Britain would be responsible for the overall policy of guided weapon development and would undertake the basic guided weapon research and development; she would supply the various weapon prototypes for trials, and would undertake their subsequent production.

The accommodation Australia has provided includes workshops for the use of United Kingdom firms which are contractors to the Ministry of Supply for the development of the various guided weapons and which test them on the ranges. At present, some ten firms from among Britain's leading aircraft and electronic manufacturers are established within the premises of the Weapons Research Establishment.

These firms, and much of the joint project activities, rely a great deal for the movement of equipment and personnel on an air ferry service operated by Royal Air Force Transport Command between Lyneham, Wilts, and Edinburgh Airfield, Salisbury, which is part of the Salisbury Establishment. Aircraft, mainly 'Hastings' and 'Comets', supplemented by chartered aircraft, provide a service at about weekly intervals.

Within the Weapons Research Establishment the scientific staff is divided into two wings, one of which is concerned with trials and instrumentation requirements arising from the guided weapons programme, and the other with research and development in fields of aerodynamics, electronics and rocket propulsion for the Australian defence departments.

Each series of guided weapons trials begins with the planning of the facilities that will be required to carry them out. Although much can be done by correspondence between the United Kingdom and Australian technical establishments involved, it is usual for the requirements to be specified in a document which results from round-table conferences in the Weapons Research Establishment, to which the Ministry of Supply and the contracting firms send representatives. The provision of these facilities follows according to the agreed time-table, and later the weapon prototype arrives from the United Kingdom in the charge of technical staff responsible for the trials. Together with Establishment staff, this team produces a detailed specification of all aspects of the individual trials that are to be done, and this is forwarded to the resident staff for implementation.

Many of these trials require the co-operation of aircraft for a variety of purposes, including the provision of pilotless target aircraft. These services are provided by the Royal Australian Air Force Air Trials Unit, which operates from Edinburgh Airfield and Woomera, with headquarters at Edinburgh Airfield, Salisbury. Two airfields have been provided at Woomera. One of them, Evetts Field, is located adjacent to the range head for the operation of the target aircraft ('Jindivik', 'Meteor' and 'Canberra').

Woomera is a town of some 3,000 inhabitants 300 miles to the north-west of Adelaide. It can be reached by rail, road and air, and is maintained in arid surroundings by a water pipe line from the River Murray about 400 miles away. Despite its location, the amenities of living have been provided on a scale which is generally acceptable, and no real problem is encountered in persuading staff to undertake terms of duty there.

The associated testing ranges are laid out over a large tract of country. The main missile range starts from a point some 25 miles from Woomera town and extends in a north-westerly direction to the far coast of Western Australia about 1,250 miles away. Longer range firings to points beyond the coast can be

conducted as required. The whole of the territory near the firing line is virtually uninhabited barren country with no large centres of population nearby.

The actual conduct of a trial once the preparation phase is ended is a swift event at any one location, but extends over many miles of territory. This necessitates suitable deployment of the range instrumentation and its maintenance in a state of high reliability and effectiveness.

The quantities to be measured in these trials are concerned with events occurring within the missile itself during flight, with the response of the missile to manipulation of its guidance and control systems, with its trajectory and attitude during flight, and with the performance of its homing system, accuracy of engagement of target, and so on. The apparatus required to effect these measurements includes various forms of telemetry and internal recorders, and ground-based optical- and radio-tracking and velocity-measuring equipment. For many purposes the subsequent recovery of the rocket is a valuable aid to a diagnosis of its behaviour. The ability to make such recoveries is one of the outstanding advantages of ranges over land, and has been exploited at Woomera in a number of ways which in special cases ensure that missiles will neither be lost nor badly damaged.

Among the optical systems in use on the ranges are tracking kine-theodolites (Fig. 2), which record the position of the missile on successive frames of film as a basis for trajectory determination, and large fixed photo-theodolite cameras which, by a series of exposures of a single plate, enable the height and ground-speed of high-flying vehicles to be measured with great precision. In addition, high-speed cine-cameras fitted with telephoto lenses, and carried in power-operated mounts for smoothness of tracking, enable changes of attitude and performance to be examined at selected points along the trajectory. Highly specialized ribbon-frame cameras have been developed for measurements of velocity and acceleration in the early stages of flight. The determination of miss-distance between a missile and target is obtained either from ground photography or from a system of cameras carried in pods at the wing tips of the target aircraft. These cameras have unique properties which include wide-angle lenses with angles of view exceeding 200°, a pair of them providing complete cover of the volume of sky surrounding them.

The electronic instrumentation includes a missile tracking system in which a radiating oscillator is carried in the missile, and a number of auto-follow ground receivers deployed along the range transmit angular information to centralized automatic plotting tables. Various radars and continuous wave apparatus for the measurements of velocity by Doppler methods are also used. A large effort is concentrated in multi-channel telemetry which provides detailed records of the internal operation of the missile during flight.

From this multiplicity of optical and electronic equipment a vast amount of magnetic tape, film and paper is accumulated, on which the events of the trials are recorded. A data reduction system has been developed and installed at the Salisbury Establishment, based upon a large digital computer called WREDAC, which can process this data at high speed. So far as possible, records are obtained from the ranges on magnetic tape which may be fed into the data reduction machinery directly. In the case of film records, semi-automatic film readers are used for enabling the records to be transformed into forms suitable for mechanical computation with the least possible delay.

In June 1957 a conference on data reduction and automatic computing machines was held at the Establishment and attended by delegates from the United Kingdom and the United States, at which the capabilities of this system of data reduction were demonstrated and a wide range of allied subjects was discussed. Proceedings of this conference are shortly to be published by the Establishment.

A continuous effort is maintained in the investigation of techniques of measurement and recording, and the analysis of the physical processes occurring in trials work ; also in the development, manufacture and utilization of equipment and systems of apparatus for use on the ranges. Effort is also devoted to the investigation of complete missile systems and guidance and control systems both through field experiments and theoretically, the latter with the use of analogue computers. Several analogue computers are in use in the Establishment, including a general-purpose machine of high accuracy called AGWAC.

Research and development work of this nature requires substantial and versatile engineering support. The workshop organization at the Weapons Research Establishment is therefore extensive. The civil engineering work required in the construction at the ranges is carried out under the direction of the Commonwealth Department of Works in accordance with plans and specifications prepared to meet the general specifications of the scientists and engineers at the Weapons Research Establishment.

To facilitate the close liaison needed between the United Kingdom and Australia in the planning of this joint undertaking, the Ministry of Supply has established a nucleus of staff in the Melbourne head office of the Department of Supply adjacent to the latter's Research and Development Branch. A detachment of this United Kingdom staff is also established within the Weapons Research Establishment at Salisbury.

The major part of the activities of the Weapons Research Establishment is thus concerned in the equipping and operating of the missile ranges at Woomera in step with the needs of a continuing and growing activity in British guided-weapon development. The Australian defence organization also has a need for scientific research and development, and

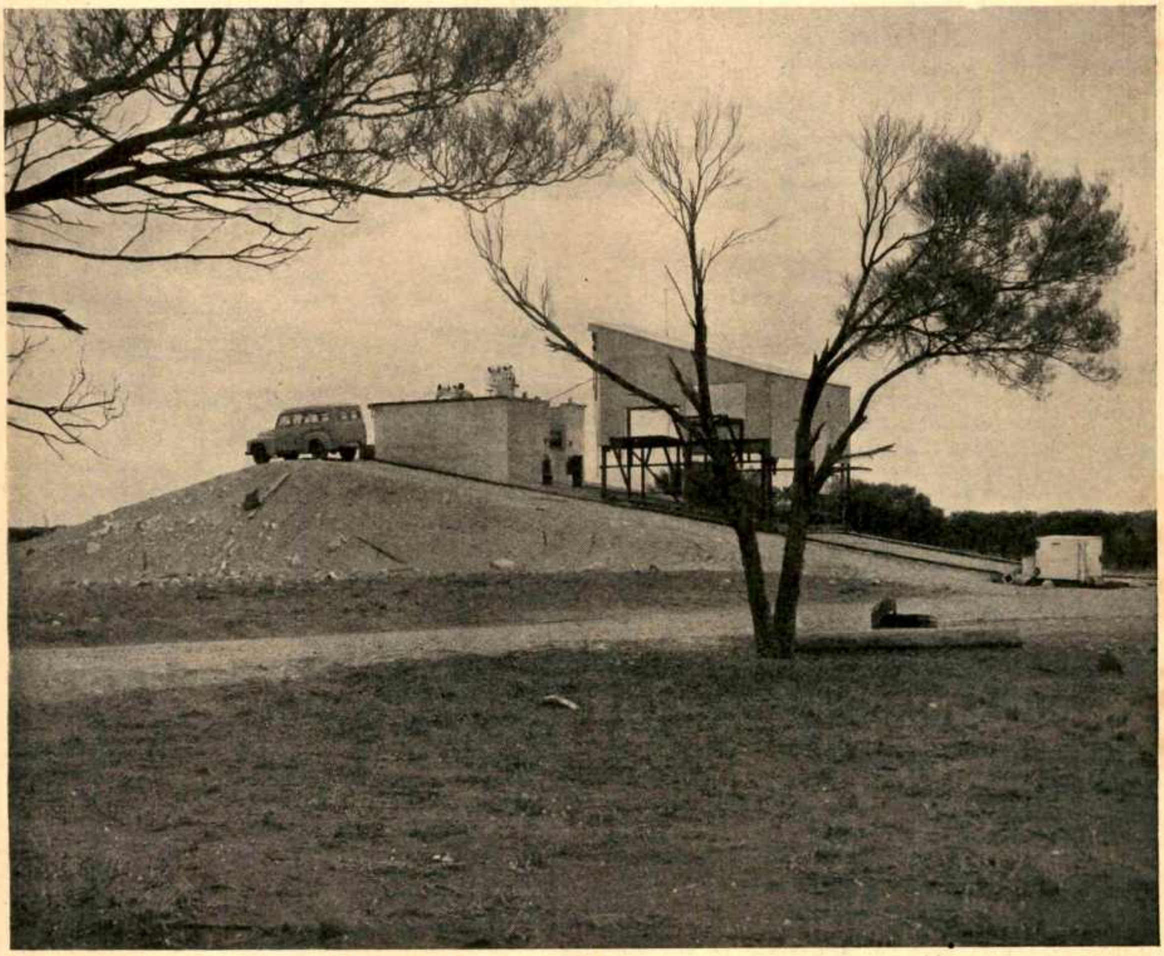

Fig. 2. A kine-theodolite post on the Woomera Range with sliding cover removed ready for use of the theodolites

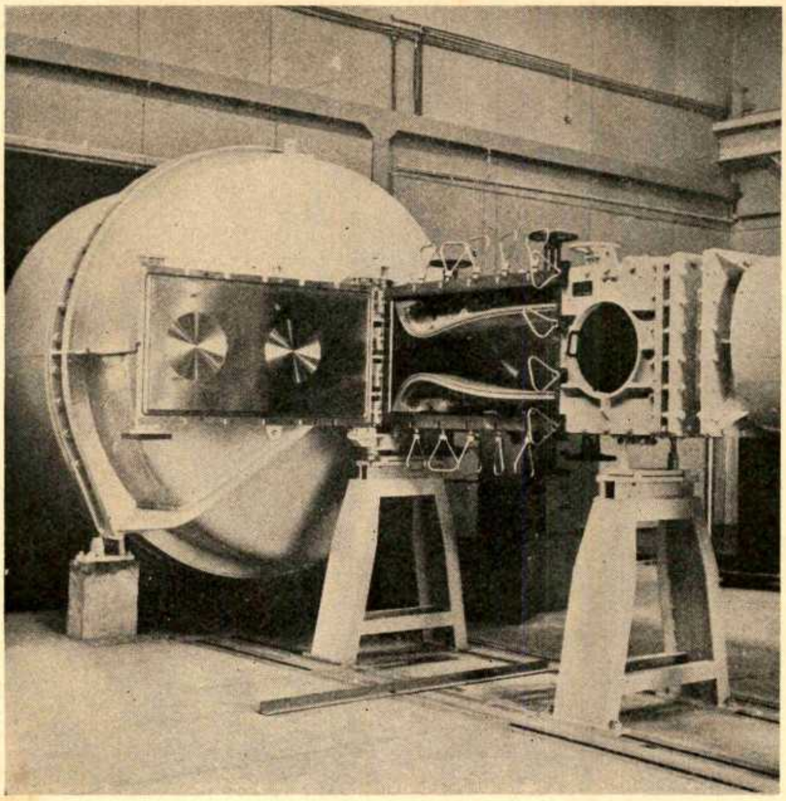

Fig. 3. 15-in. square working section of wind tunnel for Mach numbers 1·4–2·8

this is partly met by the other laboratories of the Weapons Research Establishment.

Research and Development

In Australia, defence science dates in the main from the Second World War. Prior to this, with the exception of the Munitions Supply Laboratories, there was no particular organization equipped to deal with the scientific aspects of warfare, and consequently when the emergency arose the Council for Scientific and Industrial Research, the universities and various industrial laboratories all contributed to provide the scientific effort required.

With the setting up of the Long Range Weapons Establishment in 1947, there evolved the concept of an Australian Defence Scientific Service incorporating also the Defence Standards Laboratories (formerly the Munitions Supply Laboratories) and the Aeronautical Research Laboratories (formerly a division of the Council for Scientific and Industrial Research), to undertake scientific work of a military nature. Certain other specialist laboratories also established in South Australia were incorporated into the Long Range Weapons Establishment in 1955 to form the present Weapons Research Establishment. The scientific staff of these three major establishments and the Research and Development Branch of the Department of Supply now constitute the Australian Defence Scientific Service. The Establishments are controlled by the Research and Development Branch under the direction of the Chief Scientist of the Department of Supply.

The research fields in which the Weapons Research Establishment research and development laboratories are engaged are high-speed aerodynamics, electronics and rocket propulsion. Jointly these laboratories now comprise the Research and Development Wing of the Weapons Research Establishment and are engaged primarily on research projects originated within Australian defence organizations.

The high-speed aerodynamics research is centred in two main facilities, the Woomera Rocket Range and two supersonic wind tunnels at Salisbury. There are many problems for which the free-flight technique offers particular advantages, and the facilities available at the Woomera range for this type of work are being exploited. The range is fully equipped with optical instruments for observing behaviour and tracking, with Doppler radio for velocity and, by differentiation, acceleration measurements, and with ground receiving stations for recording telemetered information from airborne transducers. Projects undertaken on the range have included the investigation of aerodynamic characteristics of rocket-boosted free-flight models, the investigation of the transonic 'area-rule', drag of wing plan-forms at transonic speeds and the flutter characteristics of rectangular wings with various mass distributions.

The 15-in. square continuous flow tunnel (Fig. 3) has a Mach number range of 1·4–2·8 and absorbs 4,000 horse-power under maximum load. The tunnel is equipped with schlieren and shadowgraph for flow visualization and multi-tube manometers for pressure measurement. Aerodynamic forces and moments acting on the model and their changes with varying incidence are measured by strain gauges and recorded in form suitable for analysis by the digital computer WREDAC. The tunnel has been in operation since March 1957.

A small 6-in. square blow-down intermittent supersonic wind tunnel for Mach numbers of 4 or slightly higher with 20 sec. duration of flow is also available.

These tunnels are used for *ad hoc* investigations and for general aerodynamic research, including the measurement of aerodynamic derivatives.

In the field of electronic research, sections are engaged in aspects of electron physics, circuit research, electro-mechanical models, and propagation studies. Applications of the non-magnetic mass spectrometer, for example, to the determination of the composition of the upper atmosphere, are being studied.

Other investigations conducted under the general heading of electronic research include the operation of double-cavity klystrons in the generation of power at micro-wave frequencies, and experiments with methods of reducing the band-width required for transmission of intelligible speech. There appears to be a possibility of achieving a band-width compression ratio of 6 to 1 with a comparatively simple system. Solid-state studies involving materials such as cadmium sulphide and amorphous selenium are in progress, with the view of their application to storage devices similar in mechanism to vidicon, but not requiring an electron beam or evacuation. The development of infra-red detectors combining sensitivity and short time-constant, particularly for wavelengths of the order 10 μ, and their use in image converters, is being studied.

In the field of chemistry also a considerable range of research and development projects is covered. Studies of the combustion of propellants for rocket motors employ the techniques of flash photolysis and shock-tubes for analysing the chemical reactions occurring and investigating the improvements to the properties of propellants. These properties, and the performance of the motors in which they are burnt, are further tested by static firings in which the thrust and the temperatures and pressures occurring within the motors are measured and recorded by a combination of optical and electronic instrumentation. The high temperatures which occur in these motors require the selective use of materials to withstand them with adequate margins of strength. Materials of the 'cermet' class are being developed for this purpose; the laboratory is equipped with the high-temperature furnaces suitable for the production of such materials. The methods of polymer chemistry are also being employed for the development of plastic and polymeric substances for use in both rocket motor components and propellants with improved physical properties, such as lightness and ability to withstand changes of operating temperature.

As a contribution to the work of the International Geophysical Year, the Weapons Research Establishment is launching two types of rocket for research in the upper atmosphere conducted by various outside research organizations. With radio equipment ('Minitrack') and a Schmidt camera provided by the United States, observations of artificial space satellites are being taken and transmitted to the satellite tracking centres in the United States. The Royal Aircraft Establishment of the Ministry of Supply has designed and built the rocket *Skylark*, which is capable of carrying a payload of 100–150 lb. of apparatus and instruments to heights up to 120 miles. This vehicle is being used by research groups from various universities in the United Kingdom, working under the auspices of the Gassiot Committee of the Royal Society, to investigate air temperatures, densities, winds, the ionosphere, and day and night air glow[1]. In addition, the Weapons Research Establishment is experimenting with the 'rockoon' technique, in which the rocket is launched from a balloon after being lifted to an altitude of 30,000–40,000 ft.

Although the Weapons Research Establishment is primarily engaged in work arising from the joint United Kingdom–Australian agreement for the testing of guided missiles on the ranges at Woomera, it will be clear from the foregoing that the Establishment also conducts a substantial programme of Australian research and development in the field of defence science. The overall Australian defence research effort is, of course, considerably amplified by the work of the other defence research establishments which are centred in Melbourne.

---

ISAAC NEWTON — CRIME INVESTIGATOR

By Sir JOHN CRAIG, K.C.V.O., C.B.

Formerly Deputy Master and Comptroller, Royal Mint

DR. ISAAC NEWTON was appointed warden of the Mint, with effect from March 25, 1696, during the great silver recoinage, in which historians from Macaulay to Profs. Temperley and Ogg give him a principal role. Their discrepant tributes are all false.

Money in England meant gold and silver coin. In principle, face and bullion value were identical. Unfortunately, grained or lettered rims dated only from the reforms of 1663, and the active silver circulation was mainly composed of worn coins struck long before by outmoded methods. Snipping a sliver of silver off their edges was organized wholesale from the reign of James II by those who handled coin in great quantities. By 1695, repeated small subtractions had robbed the silver circulation of between a third and half of its proper weight. A crisis of confidence set in; recoinage in a modern format had become inevitable.

Since the lost metal amounted in value to a year's revenue, there was a prolonged public controversy on whether it was worse to reduce the legal weights or the numbers of silver coins; whether, in fact, to devalue or deflate. A Commons Committee voted early in 1695 for a slightly disguised 10 per cent reduction of weights. Charles Montagu, Chancellor of the Exchequer, taking with the City of London the opposite view, evaded action. In the autumn, City magnates, scientists—among them Newton—and others were individually consulted. Newton, in view of a rise in the price of silver bullion since the spring, sought a reduction of coin weights by 20 per cent coupled with price control for the duration of the war[1]. His views were totally rejected; Montagu carried his own through Parliament in December.

Moreover, the enabling laws had been passed, the work begun and the Mint's machines and labourers trebled, before Newton was offered his appointment to the most dignified but least effective of the three principal offices of the Mint. Its duties were judicial and negative and it had been a sinecure for a century. Montagu's offer of it on March 19, 1696, did not suggest change. The proposition was "a good proof of my friendship. . . . The office is most appropriate for you. It is the chief officer in the Mint. It is worth £500 or £600 a year, and has not too much business to require more attendance than you may spare"[2].

The emoluments were, in fact, about £415 a year. Further, when, not pleading the letter but because other salaries in the Mint had been greatly raised for the recoinage, Newton asked for an increase for dignity's sake, the Chancellor's own department deferred decision until the recoinage was over; then, in August 1698, it gave him a lump sum[3] of £500, much the same in proportion as his colleagues.

Last, the Commons Committee on the Miscarriages of the Mint[4] explicitly stated on April 8, 1697, that the successful management of the recoinage was entirely due to the assistant master.

Newton's appointment was a piece of jobbery for a distinguished friend. Such benevolence may have been in mind for some time; it was reported in November 1695 that Newton had been appointed master[5], and in March 1696 it was rumoured that he would be appointed comptroller.

Though Newton took accommodation near the Mint in April or May, he moved in a few months to what was then the extreme west end of London, half an hour away. He retained his Cambridge professorship for the next four years. A small book of my own[6] has set out his activities then and later, but further examination shows that work arising out of coinage crimes was under-stated.

The place of a detective force was sporadically supplied by individual ministers, officials or justices of the peace and common informers, amateur or professional. So far as coinage offences were concerned, such inquiries had been run by a succession of warden's extra clerks; no warden before or after Newton touched this work. But in the May after his appointment, the extra clerk of the moment, George Macey, disappears; and then, if not before, the new warden stepped into the breach.

He was already well acquainted with the underworld by July 30, 1696, when he was summoned before the Lords Justices, the central body of government in the King's absence at the war, to unravel a complicated web of charge and counter-charge. A counterfeiter called Cooke, being condemned to death, bought a respite in May by betraying a number of other criminals and accusing one William Chaloner of theft of dies from the Mint. Chaloner, who was himself seeking a pardon for earlier misdeeds, told the justices that the officials of the Mint themselves supplied dies, tools and false guineas to counterfeiters. Scotch Robin, of the engraver's section, accused Thomas White of the thefts and fled to Edinburgh; White, already under sentence of death for a different crime, accused Hunter and offered information against other criminals.

As Newton investigated this imbroglio, one betrayal led to another until the accused on his hands rose to more than thirty. He interviewed at least half a dozen of them; apart from intermediate correspondence, he attended eight meetings of the Lords Justices, by whom he was further commissioned to examine the security system of the Mint[7]. All this was during the two months of August and September 1696. Other investigations are revealed by an entry in his expense account[8] for September 11, "paid Humphrey Hall to buy him a suit to qualify him for conversing with a gang of coiners of note in order to discover them, £5".

His appeal to the Treasury to be relieved of this attorney's work reveals that he had no assistant and that he interviewed personally prisoners and Newgate solicitors[9]. On November 17 the Treasury sanctioned an extra clerk at £60 a year on the ground of Newton's extraordinary work in detecting and prosecuting clippers and coiners, but the authority may have been anticipated, for the Lords Justices had agreed on August 26 that an assistant was needed, and the salary of Christopher Ellis, the clerk whom he chose, was paid from September quarter day[10].

Newton declared in 1697, what other evidence supports, that his activity had driven many counterfeiters out of London into the provinces beyond the reach of his agents; but the criminal work remained substantial.

The provinces were not neglected. Once at least, on June 9, 1698, he attended at the Treasury to advise on counterfeiting in Yorkshire. In September 1696 he had paid Charles Maris £44 2*s.* for services in Worcestershire and Shropshire; during the summer, another agent, Bodenham Rewse (afterwards head turnkey of Newgate gaol), was paid £34 for prosecutions in these and three other western counties; in March 1697, £40 rewarded Caleb Clark and Joseph Williams for arrests and convictions at Worcester and Exeter; in 1698, Christopher Priddick received £27 7*s.* for convicting seventeen persons out of forty-three charged[11]. Other agents were Taylor, a Holborn engraver, Benjamin Harris, and a little later, John Snow, Botiler, Robert Saker and Richard Morris, who was eventually rewarded with a post in the Mint.

The theft of Mint dies produced a Commons Committee with wider terms of reference to include all "miscarriages". Newton gave the chairman privately a draft Bill for improving the legislation against crime. Amended by the Judges, it was passed during the session[12]. Chaloner, called as a witness, repeated accusations of corruption and inefficiency. The essential reform was to put a practical all-round man in charge of the Mint. To show where this man could be found, he announced two inventions of his own to make counterfeiting impossible—a groove, enclosing a suitable design, in the edges of coins, and an extremely high relief. He undertook to adapt the Mint presses with an enormous future saving.

The Committee was favourably impressed and ordered Newton to bring tools and gear in five days time for Chaloner to demonstrate his methods. Newton, bound under oath not to disclose certain secrets of coining, refused. Neither could he admit the witness to the Mint. But he had pattern sixpences, shillings and half-crowns prepared in high relief and with grooved edges. In the light of this experiment, he assured the Committee that Chaloner's suggestions were expensive, impracticable and useless. These findings were undoubtedly correct. Nevertheless, the Committee reported bluntly on April 8, 1697, in favour of Mr. Chaloner's "better, securer and more effectual way" of coining[13].

Newton in his mortification promised to hang Chaloner, who blamed the final fulfilment of this threat on continuing rancour. It may have been so. Four long holograph memoranda in the Portsmouth collection are devoted to Chaloner[14]; Newton deals there with no other criminal with one minor exception. But the next clashes of the two were accidental.

In August, Newton was called to the Secretary of State's office to examine a suspected counterfeiter, from whom he learned that Mr. Justice Negus had been given full details on May 18 by one of the gang, John Peers, of coinage planned under Chaloner's direction with a new amalgam and improved moulds at Egham, as London had become too risky. He had Peers hauled to the Mint under arrest on August 13, 1697; but as nothing vital had yet been done, released him with a gift of 5*s.* to wait and watch. Peers's visit to the Tower, however, had been noticed, and another of the group had him arrested for counterfeiting. The angry warden visited Newgate next day and bailed out his witness. About the same time he arrested and examined without result a third member of the gang, Thomas Holloway.

On August 31 Newton was called in by the Lords Justices to advise on life or death for the counterfeiter Hicks. He trod on the heels of Chaloner and his old confederate, Aubrey Price, who had brought a ludicrous story of a Jacobite plot to seize Dover Castle, and a scheme for their own employment as Jacobite couriers, in order to compile lists of the disaffected. Newton revealed the two men's histories and was instructed to arrest them. After a protest that, though building up a capital charge against Chaloner, he could as yet only convict him of a misdemeanour, he clapped the pair in Newgate on September 4. Then Chaloner informed on Price, Price on Chaloner, and two other rogues added denunciations. The Lords Justices showed a great appetite for detail; Newton had to attend five of their meetings to help them. Finally, he asked through the Treasury whether in Chaloner's case he could go back beyond his pardon and was cynically advised by the highest legal authority to discredit the accused over the misdemeanour and proceed to the graver charges when the jury had been biased[15].

During the delay Chaloner suspected trickery, and promised the most dangerous witness against him, Thomas Holloway, £20 to move to Scotland; Newton elicited all the details afterwards. The two other witnesses recanted and Newton's case was summarily dismissed[16].

Chaloner protested to the new Parliament against this high-handed imprisonment in chains, for revelations against the Mint, of a witness before a Commons Committee[17]. A Select Committee was at once set up, on February 18, 1698. The charge of breach of privilege might have been perilous. Newton went over Chaloner's career, exposed some of his lies and defended the arrest, with dates, as unconnected with the previous Committee, but necessary to anticipate a "new and dangerous" way of coining by a notorious criminal. The Lords Justices were not mentioned. Sympathetic at first to the appellant, the Committee found in Newton's favour in terms which he complained were far too brief. Passing to other topics, they compelled his attendance on at least four days in April and May on the accounts of the recoinage[18].

Some time after July 9, 1698, Newton set up his new system of criminal records[19]. This volume contains his examinations of a very large number of criminals, but disproportionate space is devoted to Chaloner, and a number of letters are included, which is done in no other case. It may well have started with an entry a quarter way through of evidence taken against him on October 12, 1698, previous pages being left blank for retrospective entries. Newton's procedure is clear. A witness or suspect was brought before him in the Mint, sworn and questioned; Newton wrote down or dictated a summary of the answers—this is clear from occasional use of the first personal pronoun for the warden. The statement was read to the deponent, who, if necessary, qualified or extended it, and then signed or made his mark. Newton countersigned. Some time after, the accumulated statements were copied into the book. A number were certainly missed; only about half the deponents known from accounts or memoranda appear. Even so, it shows that Newton attended at the Mint for this purpose on at least 127 days from June 1698 to December 1699. The intensity rose to a climax in February 1699, when the Chaloner case was at its peak, with eighteen days attendance, ten of them in succession and including Sundays. This was the "King's business" with which Newton excused himself to Flamsteed in the famous letter of January 6, 1699.

A forgery by Chaloner of Malt lottery tickets, a kind of government premium bond, for which he was betrayed and arrested in October 1698, had nothing to do with the Mint or with Newton. Nevertheless, he collected and had transcribed all the evidence about it, and tipped the useful witnesses. Slowly at first, but much more intensely after the turn of the year, he gathered information about Chaloner's coinage crimes. He even employed in succession, one after the other, as each was seen through by Chaloner, three men whom he had committed to Newgate for crimes, to worm their way into the suspect's confidence and pass on his admissions. Stranger still, he met one of these men in a public house near the prison for oral report and instruction[20].

When after these delays Chaloner was put on trial on March 2, 1699, at the Old Bailey, the lottery ticket forgery was dropped. Newton instead laid three indictments against him: (1) that he had suborned on September 13, 1697, the witness Thomas Holloway to fly; (2) that he had made twenty counterfeit French gold coins in Middlesex on August 25, 1698; (3) that on that day and in that county he had made 10 false guineas, 20 crowns, 40 half-crowns, 20 shillings and 10 sixpences[21].

None could think that 100 counterfeits in two metals and five denominations were made in a single day. The trial proceeded on the third and only capital charge. Newton's six witnesses, all of them criminal and disreputable, were allowed to roam over the past six years without precision as to time or place. Apparently the nearest offence, and that in Surrey, was of forging some shillings in June. Common sense triumphed over the niceties of the law. The jury found Chaloner guilty and he was sentenced to be drawn on a sledge to Tyburn and hanged.

A piteous letter[22] to Newton, detailing all the irregularities of the trial and the prisoner's innocence, had no effect and Chaloner was hanged on March 22, 1699. His gift to Newton at the last moment was grotesque: it was the copper plate for forging the lottery ticket.

Newton continued these pursuits on a diminishing scale until June 1700, six months after he had become master and had been replaced by a new warden, and he resumed them for a short period in 1704. Detection may, after all, have had some appeal for him.

Seven of Newgate's inmates in March 1699 had been committed by Newton, and he probably imprisoned more than a hundred criminals in London alone. A small minority were hanged. Thirteen men and two women were executed in London for coinage offences in 1697; the total fell to eight in 1698[23]. It may be a mere coincidence that London executions for coinage offences practically ceased from 1700 for a few years. The cost was small, less than £300 a year, apart from the large statutory awards given by the Treasury. In addition, Newton was paid his bill for £120 for various small expenses, apparently personal, on coach hire and in taverns, prisons and other places during his wardenship[24].

In the light of the corruption, disorder and chaos which he had experienced, Newton evolved at an unknown date a detailed proposal for a board "above the reach of ordinary corruption" with salaried indoor and outdoor staff wholly financed by the Treasury and unconnected with the Mint, to centralize all evidence, manage all prosecutions throughout the country, and advise on all pardons. Non-co-operative justices of the peace were to be dealt with through neighbouring benches and the Lord Chancellor[25].

So sweeping and costly a change was not likely to be accepted forthwith; but Newton inserted the thin edge of the wedge in 1715 by the appointment of a solicitor in place of the extra clerk, and the prescription of a scale of fees for each type of case. The ponderous department of the Mint solicitor grew out of this germ. It established a country-wide system, and centralized co-ordination and control long before most of its work was handed over to the new police in 1851.

EARLY WRITING IN GREECE

TABLETS of baked clay inscribed with short statements in two unknown scripts of the later Bronze Age (which in the eastern Mediterranean ended about the eleventh century B.C.) were found in Crete around A.D. 1900. Sir Arthur Evans, their discoverer, named the earlier script Linear *A* and the later Linear *B*. A few examples of Linear *B* were also recognized on the mainland of Greece, but it was not until 1939 at Pylos and 1952 at Mycenæ that the Greek finds became considerable. From the first, it was apparent that many of these tablets were accounts and the numerical system was soon worked out. The other signs number between eighty and ninety and occur in small groupings, so that it was reasonably inferred that they represented syllables and not single consonants and vowels. Though a few entries were accompanied by rough but sometimes recognizable sketches of objects (ideograms), the language was not deciphered; but since Bronze Age (or Minoan) Crete was believed not to be Greek, it was concluded that the language of both Linear *A* and Linear *B* was not Greek either.

The decipherment of the tablets by themselves, though occasionally attempted, was generally considered impossible, and indeed relatively few of them were published. But in 1952, a young British architect, Michael Ventris, who had been working on the problem over a period of sixteen years, announced a solution of Linear *B*. By studying the distribution of the signs he deduced something about the system of grammatical inflexions and the relationships between several of the syllables: if, for example, groups of signs occur which differ only in the last syllable, then there is some likelihood that those last syllables begin with the same consonant and terminate with different vowels. Next he tried to fit ancient Cretan place-names into this framework, and so obtained provisional values for some syllables. The application of these values to other words gave results that looked like Greek, and by experiment values were assigned to most of the other syllables. For the interpretation of his results, Ventris collaborated with an expert on Greek language, John Chadwick, who has continued the task after Ventris's early death. Their "Documents in Mycenæan Greek" is now a standard work.

The Greek obtained by Ventris is at first sight curious. Greek is not a language that lends itself to a syllabary of the type of one consonant plus one vowel, and so final consonants are omitted. Secondly, the deduced syllabary does not distinguish between *l* and *r*; *b* and *p* and *ph*; *g* and *k* and *kh*; or *t* and *th*: so, to take a very extreme case, *pa-te* stands for *pater* and *pantes*, and could stand for some hundreds of permutations conceivable by the rules of Greek word-structure. Thirdly, the vocabulary and grammatical inflexions differ considerably from those of the next Greek documents, composed some 500 years later in the eighth century B.C. Fourthly, the texts of the tablets, as is natural in brief notes, do not often have a normal syntactical form.

In spite of these difficulties, most classical students have accepted the solution of Ventris and Chadwick. They argue that the decipherment works, that for historical reasons Greek was probably spoken in mainland Greece in its Late Bronze (or Mycenæan) Age, when these tablets were written; that their dialect resembles Arcadian, which geography suggests was descended from a dialect spoken in Bronze Age Greece; that some of the word-forms, titles and names were to be expected from linguistic evolution and later legends; and, more cogently, that after the decipherment was published new tablets were found with sketches of objects and descriptions written beside them, and these descriptions make good sense. The disbelievers allege that the proposed rules of spelling are so elastic that Greek of some sort could be read out of almost any hotch-potch of syllables, and that even so, the transcriptions offered are barely, if at all, intelligible. Though some scepticism in detail is needed, it seems to me that in principle the decipherment is convincing.

Any new theory is likely to attract some embarrassing supporters, and many of the interpretations of the tablets are exaggerated or even silly. The tablets so far known number altogether about 5,000, and most are fragmentary. They are, when complete, flat slabs of clay in sizes generally from 16 cm. × 3 cm. to 30 cm. × 15 cm. and contain from about a dozen to 180 signs. They were used for accounts and short records and, since they were originally unfired, were not meant to be kept long. Those that survive do so by virtue of the accident that the room where they were was burnt down. From this it follows that the tablets we have do not form continuous series, but are, in fact, sets of the same date. The conclusions drawn from this unpromising material are first linguistic, secondly historical.

For the earlier development of the Greek language and changes in vocabulary the tablets are obviously important, though they give little evidence on syntax and many of the forms are ambiguous. They also explain some traditional phrases in Homer, and show that Semitic loan-words had been accepted in Greek by the thirteenth century B.C. Philologists in general appreciate the limitations of this material and their claims are reasonable.

It is very different with historical interpretations. When they speculate on periods that are not fully historical, too many classical students (and prehistorians) cultivate a fundamentally uncritical ingenuity, and the obscure hints of the tablets are a tempting bait. The favourite topics for exegesis are social classes and land tenure (on which, it seems to me, the present evidence is inconclusive) and the relation between Mycenæan society and that presented 500 years later by Homer (which is, in my opinion, tenuous). What is certain is that the ruling groups of Mycenæan Greece used the Greek language, that they worshipped most of the later Greek deities, that some of the names of personages in later Greek legends were current in Mycenæan times, and that there were Greek rulers in Late Bronze Age Crete. Some time in the future, perhaps, a longer document or treaty will turn up to provide more historical illumination. Whether the Mycenæans should be considered as Greeks is another problem, which depends partly on definition. They spoke Greek and were ancestors of the historical Greeks, but their culture was very different, antecedent to but not perhaps significant for the development of the culture which we normally mean when we speak of Greek or Hellenic.

The volume* the appearance of which has provided the occasion for this article almost completes the publication of all the tablets found up to last year. A. J. B. and E. B. Wace explain the circumstances of their finds, Bennett illustrates, describes and transcribes precisely, and Chadwick comments with careful judgment. Incidentally, there is some useful information for the history of botany. The indexes are full. The evidence is now admirably presented for other students to use or misuse.

R. M. Cook

OBITUARIES

Viscount Bledisloe of Lydney, G.C.M.G., K.B.E.

On July 3, Viscount Bledisloe died at his home at Lydney, Gloucestershire, in his ninety-first year. He was one of the first members of Parliament to take an interest in agricultural science, when rather more than fifty years ago it was breaking away from the ideas of the mid-nineteenth century that had long dominated it and began to develop on modern lines. In its earlier days, agricultural science had been largely concerned with finding solutions to farm problems; it had almost reached a dead end. The new purpose was to study the relations between the growing plant and its environment without regard to whether the results might have any bearing on agricultural practice.

Lord Bledisloe, then Charles Bathurst and member of Parliament for Wilton, was one of the few in authority who recognized the soundness of this approach. British agriculture was very slowly beginning to emerge from a severe depression that had lasted for some twenty years, and he constantly urged the Government to help it; he was almost alone in this, but he never lost heart. The Government went so far as to promote agricultural education, but would do nothing for the new type of agricultural research. He realized that agricultural education, to be effective, must be based on a sound agricultural science, and when finally the Lloyd George Development Fund was set up, out of which research could be financed, he actively supported the first expansion of Rothamsted Experimental Station in 1912. Later, as chairman of the governing body of the Station, he was a frequent visitor to the laboratories and made a point of knowing the members of the staff and the chief lines on which they were working. A new block of laboratories for plant pathology was built during his term of office. As chairman, his policy was to maintain the links between agricultural science and agricultural practice. This was acceptable to the leaders of the new science, who realized that it would inevitably become increasingly complex, and might, unless care were taken, become lost in the infinite spaces of pure science.

He was equally interested in the application of science to the improvement of animal health, and did much to ensure that the new knowledge should reach even the small farmers. One of the results has been the elimination of tuberculosis from many dairy herds and even from an entire county.

In 1928, he became chairman of the Imperial Grassland Association and took an active part in the awakening of interest, both practical and scientific, in the grasslands of the Commonwealth, which has led to remarkable developments in many countries. This work, however, he soon had to give up, as he was appointed Governor-General of New Zealand. The choice was a particularly happy one. He was peculiarly well qualified for the post, and filled it with great distinction, aided by his charming wife. His lively interest in the pastoral industry, New Zealand's chief source of wealth, based on personal knowledge and experience of livestock gained on his farm at Lydney, enabled him to meet farmers on their own ground, and his obvious pleasure in making direct contact with them greatly endeared him to them. His interest in the scientific workers and their problems was equally marked, and equally rewarded.

Lord Bledisloe will long be remembered with affection by those who were privileged to know him, and with deep respect by the many who in farms, villages or research stations had benefited by the encouragement he always gave to those trying to raise the standard of country life.

E. John Russell

Dr. Rosalind E. Franklin

The news of the death of Rosalind Franklin on April 16 came as a shock to many workers in the field of biochemistry and virus studies. It is a special tragedy when a brilliant research worker is cut off at the height of her powers and when exciting new discoveries are expected from her.

Rosalind Franklin was born in London on July 25, 1920, the elder daughter of Mr. and Mrs. E. A. Franklin. She was educated at St. Paul's School, London, and Newnham College, Cambridge, and started her scientific career after studying physical chemistry at Cambridge. Her first employment was in the British Coal Utilization Research Association, where she worked under Bangham on the colloidal properties of cokes and chars. She showed that although the total volume of the pores in the coal increases continuously with increasing temperature, their accessibility decreases, so that finally even helium molecules are unable to penetrate them.

It must have been apparent to her then that it would be impossible to reach an understanding of coals and chars without the use of X-ray diffraction methods. These she was able to acquire when she transferred in 1947 to the Laboratoire Centrale des Services Chimiques de l'État in Paris. Her three years in Paris working with Méring taught her to appreciate the value of monochromatic X-rays for low- and high-angle studies of amorphous substances where bands of indefinite intensity replace the sharp spots given by the more perfect crystals. It was, however, a combination of these analytical techniques with chemical preparatory skill that enabled her to unravel the major processes concerned with the transformation of practically all organic substances into different kinds of chars on heating. In a series of beautifully executed researches she discovered the fundamental distinction between carbons that turned into graphite on heating and those that did not, and further related this difference to the chemical constitution of the molecules from which the chars were made. These studies are of fundamental interest both for the old industry of coking and for the new one of graphite moderators in atomic piles.

Miss Franklin might well have remained in this field in which she had made her name, if she had not been more attracted to that of biophysics, where she was able to turn her newly developed skills to investigate the structure of large molecules of biological importance, particularly in nucleic acids and the viruses.

In 1951 Miss Franklin was awarded a Turner–Newall Fellowship to work at the newly established Biophysical Laboratory at King's College, London. Without any previous biological experience, but with a great grasp of X-ray techniques and their chemical implications, she arrived at a fortunate moment, when X-ray crystallography was breaking away from the more limited field of the study of regular crystals to those in which the molecules were only partially ordered, and in particular those in which the essential form was that of the spiral. Her first paper in this field was one of three in which the first was the now classical paper of Watson and Crick on the double-spiral hypothesis for the structure of deoxyribonucleic acid. In this close collaboration between the Cambridge and London schools it is difficult to disentangle all the contributions of individuals, but what Miss Franklin had to give was the technique of preparing and taking X-ray photographs of the two hydrated forms of deoxyribonucleic acid and by applying the methods of Patterson function analysis to show that the structure was best accounted for by a double spiral of nucleotides, in which the phosphorus atoms lay on the outside.

In 1953 Miss Franklin left the Unit at King's College to take up the direction of research on virus structure at Birkbeck College, London, where her work was supported first by the Agricultural Research Council and later by the United States Department of Health. Here her main study was on tobacco mosaic virus. She took up its X-ray study where it had been left in the work of Bernal and Fankuchen fifteen years before, using her improved techniques. Watson had put forward the hypothesis that the virus structure was also spiral, but one of quite a different order from that which existed in proteins and in deoxyribonucleic acid. Miss Franklin, with the help of very much better X-ray photographs than had hitherto been obtained, was able in essence to verify this hypothesis and to correct it in detail. It was at this point that the extremely fruitful co-operation began between Miss Franklin's unit and Fraenkel-Conrat at Berkeley, Caspar at Yale, and Schramm at Tübingen. Using the method of isomorphous replacement, she showed that the virus particle was not solid, as had previously been thought, but actually a hollow tube. Miss Franklin's greatest contribution to this study was to compare the radial density map of the intact tobacco mosaic virus with that of the nucleic acid-free particles, in which the protein units had been re-aggregated without the ribonucleic acid. This showed that the ribonucleic acid was not to be found in the central cavity but embedded in the protein.

It would also appear from work still unpublished at the time of her death that the ribonucleic acid is in the form of a single strand, following the spiral of the virus particle, thus being very different from the double-wound helices of the deoxyribonucleic acid of the bacterial viruses and higher organisms. The combined methods of chemical preparation and X-ray examination in the hands of Miss Franklin and her associates was a valuable, and indeed a decisive, weapon in the analysis of these complex structures.

As a scientist Miss Franklin was distinguished by extreme clarity and perfection in everything she undertook. Her photographs are among the most beautiful X-ray photographs of any substance ever taken. Their excellence was the fruit of extreme care in preparation and mounting of the specimens as well as in the taking of the photographs. She did nearly all this work with her own hands. At the same time, she proved to be an admirable director of a research team and inspired those who worked with her to reach the same high standard. Her devotion to research showed itself at its finest in the last months of her life. Although stricken with an illness which she knew would be fatal, she continued to work right up to the end. Her early death is a great loss to science.

J. D. Bernal

NEWS and VIEWS

Atomic Weapons Research Establishment:
Dr. Nyman Levin

Dr. Nyman Levin has been appointed by the United Kingdom Atomic Energy Authority to be a deputy director of the Atomic Weapons Research Establishment. Dr. Levin, who was born in 1906, graduated at the Royal College of Science, London. During 1930–40 he was with Marconi (Research and Development) and then he was seconded to the Admiralty to work with the Royal Naval Scientific Service. He transferred to the permanent staff in 1946. He was appointed superintendent of the Admiralty Gunnery Establishment in 1951. Since 1955 he has been chief of research and development to Rank Precision Industries. When he joined the Admiralty, Dr. Levin was engaged on the development of microwave valves; he started work in Bristol at what ultimately became the Services Electronics Research Laboratory. He carried out development work on microwave receivers and then was responsible for the establishment of cross-channel V.H.F. links, as part of the preparation for the invasion of Europe. This involved building a chain of stations along the south coast of Britain and confirming the reliability of V.H.F. communications over very long distances. Soon after the War ended he became head of the Instrumentation Group at the Admiralty Research Laboratory, where the underwater television technique was developed. With Rank Precision Industries he has been responsible for the development in Britain of xerography—a technique of dry electrostatic photocopying—and its applications, including the high-speed printing of computer outputs.

Theoretical Physics at Nottingham:
Prof. K. S. H. Stevens

Dr. K. S. H. Stevens, who has been appointed to the chair of theoretical physics in the University of Nottingham, was educated at Magdalen College School, Oxford, from which he won an open mathematical scholarship at Jesus College. After two years residence he joined the Admiralty Research Group at the Clarendon Laboratory in 1942 and returned to Jesus College in 1945. He was awarded first-class honours in the Mathematics Finals of 1947 and was Harmsworth senior scholar of Merton College during 1947–49. He obtained the D.Phil. degree for theoretical physics in the latter year. During 1949–53 he was research fellow of the Pressed Steel Company at Oxford, and during 1953–54 was in residence at Harvard University. Dr. Stevens was appointed reader in theoretical physics in the University of Nottingham in 1953. His main interests at Oxford were in the theory and magnetic properties of ionic salts, and more recently he has been concerned with the ferromagnetism of metals and alloys and other aspects of magnetism, including applications to micro-wave amplifiers.

Agriculture at Nottingham:
Dr. J. D. Ivins

The appointment of Dr. J. D. Ivins to the chair of agriculture at the University of Nottingham, vacant since the resignation of Prof. H. G. Robinson in 1954, will be welcomed by his friends throughout the United Kingdom. Dr. Ivins graduated from the University of Reading with honours in agricultural botany in 1944, and was appointed almost immediately to the National Institute of Agricultural Botany at Cambridge. His connexion with the University of Nottingham was made in 1945, when he went as crop recorder to the School of Agriculture at Sutton Bonington. He became lecturer in crop husbandry in 1948, and was invited to become acting head of the Department of Agriculture in 1955. Dr. Ivins has been an active member of the Agricultural Education Association and of the British Grassland Society, and since 1956 has been recorder of Section K of the British Association. An able and inspiring lecturer, he has already made noteworthy contributions to the welfare of the School, in the reorganization of the University farms, and by the extensive and effective liaison he has built up with numerous sections of agriculture and its related industries. At the same time he has developed and encouraged an effective school in the Department of Agriculture, where he has initiated two lines of research. The first, which arises logically from the theme of the Nottingham School, is the effect of cultural practices on the growth of the potato crop. The second, which is more peculiarly his own, is an attempt to bridge the gap between crop and animal husbandry by a study of the utilization of grass by the grazing animal. His use of small balanced herds of identical twins has given a precision to measurement that has not hitherto been possible, and the more critical evaluation of pasture productivity that results affords interesting potentialities for the future.

Chair of Heat Transfer in London:
Prof. D. B. Spalding

Dr. D. B. Spalding, whose appointment to the new University chair of heat transfer tenable at the Imperial College of Science and Technology, London, has just been announced, is well known for his work in the general field of thermodynamics and heat transfer. His research interests in the past few years have been concerned in particular with problems of temperature distribution and heat transfer in combustion processes, and with the thermodynamics and mass transfer in boundary layers, particularly in high-speed flow. He has developed and exploited a number of analogue methods for the solution of the equations that arise in these connexions, some of them electronic and others mechanical analogues in the true sense. His new appointment marks a further stage in the planned expansion of the Mechanical Engineering Department at the Imperial College of Science and Technology, as the completion of the first stage of the new Engineering block makes available some more room for experimental work in heat transfer.

Royal Commission for the Exhibition of 1851: Awards for 1958

The Royal Commission for the Exhibition of 1851 has awarded the following senior studentships for 1958 for research at the universities indicated: Miss I. C. Gardner (Glasgow), for research in plant biochemistry; P. B. Jones (Oxford), for research in nuclear physics; M. P. Kerney (Imperial College of Science and Technology, London), for research in palæontology; G. W. Kirby (Cambridge), for research in organic chemistry; P. A. G. Scheuer (Cambridge), for research in radio astronomy. The Commission has also awarded the following overseas scholarships for 1958: I. G. Macquarrie (Dalhousie University), for research in botany at King's College, London; E. A. Ogryzlo (McGill University), for research in physical chemistry at Sheffield; W. R. Frisken (Queen's University, Kingston), for research in nuclear physics at Birmingham; D. W. Cameron (University of Queensland), for research in organic chemistry at Manchester; D. H. Green (University of Tasmania), for research in geology at Cambridge; R. M. Freeman (University of New Zealand), for research in physics at Cambridge; Miss A. J. Alexander (Rhodes University), for research in zoology at Cambridge; M. E. Mitchell (National University of Ireland), for research in ecological botany at the University of Rennes; G. B. Venkata Subramanian (University of Delhi), for research in organic chemistry at Cambridge; M. M. Islam (University of Dacca), for research in physics at Birmingham.

The National Chemical Laboratory

THE Lord President of the Council has approved changes in the functions of the Chemical Research Laboratory at Teddington, Middlesex, proposed by the Council for Scientific and Industrial Research, and the name of the Laboratory has been changed to the National Chemical Laboratory. The Laboratory will concentrate its effort on a few objectives, covering only a limited part of the whole field of chemical research, so as to be able to make a real impact on selected problems of national importance such as the following: (*a*) Problems which are appropriate neither to industrial research laboratories nor to universities, because of the necessity for special facilities, experienced staff and continuity of effort. These include the determination of the fundamental physico-chemical properties of chemical compounds which are required, for example, by chemical engineers for the design of full-scale industrial plant. The related study of the development of techniques of purification of materials such as metals and chemicals, with the view of supplying standard samples of pure substances for reference purposes, is also in this category. (*b*) Problems, the solutions of which are of national economic value and have wide general applications to many industries, for example, fundamental and applied studies of the corrosion of metals, which has been estimated to cost Great Britain about £600 million a year. (*c*) Problems, the solutions of which are urgently required in connexion with the nation's atomic energy programme; these are mainly concerned with the extraction of elements of atomic energy interest from low-grade ores. The change in the name to the National Chemical Laboratory has been decided upon to emphasize that its main purpose will be to undertake selected fundamental and applied chemical researches of national importance, which could not otherwise be worked on by any existing organization.

Windscale Pile No. 1

THE Atomic Energy Authority has decided that it would not be economic to repair Windscale Pile No. 1. The maximum technical information which can be derived from examination of the reactor core is being obtained, and useful materials and equipment will be recovered. Some of the buildings will be adapted to other uses and the remainder sealed off. The operatives hitherto employed on this reactor are now engaged on other activities at Windscale which are expanding.

Moral Implications of Atomic Energy

IN his Burge Memorial Lecture delivered on April 15 at Church House, Westminster, which has now been published ("Ethical and Political Problems of the Atomic Age". Pp. 22. London: Student Christian Movement Press, 1958. 2*s*. net), C. F. von Weizsäcker discussed some ethical and political problems of the atomic age, as a scientist, as a citizen of the Western world and as a Christian. Beginning with the observation that the most conspicuous political event of 1957 was the appearance of the first Soviet Earth satellite, he points out that this technical achievement became a political event because of its psychological effect, and that such developments pose the problem of the adult man, no longer protected like a child, who can survive only if he creates for himself the conditions of life. Dr. von Weizsäcker himself believes that the spiritual foundations of the technical world are dependent upon Christianity. Pointing out that Western freedom is guaranteed only by the certainty that mortal blow will be answered with mortal blow, he maintains that this is a very precarious guarantee. After examining the measures proposed for avoiding the present dangers, he concludes that, in principle, it would be sensible to strive for the total abolition of war by all prudent means and that such attempts have a good chance of success. It is, however, the policy of the Soviet Union to undermine the strength of the West by exploiting the prevalent and understandable antipathy to nuclear weapons. The belief that such weapons will effectively protect our peace and freedom is itself a well thought-out ideology containing strong elements of truth, but its effect is to cripple our wills. Dr. von Weizsäcker does not think that the Church as an institution is in a position to suggest the renunciation of the hydrogen bomb on a basis of political responsibility; those who have already experienced something of this crisis would render their fellow-men a service by dissociating themselves from all participation in matters connected with such weapons. The value of passive resistance and of more conventional political methods requires much fuller examination.

Preservation of Rural England

THE twenty-seventh annual report of the Sheffield and Peak District Branch of the Council for the Preservation of Rural England, presented at the annual meeting on May 31, stresses the failure of Parliament to respond to the urgent plea that the Land Fund, understood to be designed for National Parks, should be put to that purpose. In consequence, the National Parks Act is ineffectual, and the same lack of vision, the report urges, is shown in the siting of nuclear power stations in the very areas the National Parks Act was framed to protect. The Branch fully supports the stand being made against the proposal to site such a station on Trawsfyndd Lake. Tribute is paid to the competent control constantly exercised by the Park Planning Board in the Peak District National Park, and the Board and the Branch are supporting the petitioners against the proposed Chew Valley reservoir, which would take all the remaining farmland and spoil the fine approaches up the Chew Valley to the moors of the National Park. With the National Parks Commission and the National Trust, the Council and its local branches have indicated their opposition to the proposed motor road in the Manifold Valley. Adverse comment is also made on the proposal to erect a steel lattice-tower 150 ft. high for a police radio transmitter and on the continuance of threats from opencast coal-mining, notably at Barlow. However, the arrangement between the General Post Office and the Peak Park Planning Board covering the whole Peak regarding proposals likely to affect the landscape, and of the Sheffield Corporation's policy towards tree planting, receive favourable mention.

International Certification of Herbage Seed

As a result of a certification scheme introduced by the Organization for European Economic Co-operation, the farmers of Europe will in future be able to rely on the qualities and types of seed for grasses and legumes offered for sale. In the past, confusion has arisen due to differences in nomenclature and methods of certification between countries. Hitherto, herbage seed offered in international trade has fallen into two categories: uncertified seed and seed certified in accordance with various national systems. The effect of the new rules and directions approved by the Organization for European Economic Co-operation is the introduction of a third category—herbage seed bearing an international certificate and a special label issued under the authority of the official seed-certifying agencies in member countries of the Organization. The scheme is open to any of the seventeen member countries and will operate for an initial period of five years. Copies of the rules and directions can be obtained from the Director of Agriculture and Food of the Organization for European Economic Co-operation.

Colleges of Technology in Britain

In a written answer in the House of Commons on June 18, the Minister of Education, Mr. Geoffrey Lloyd, listed the following colleges as approved, up to the present, as colleges of advanced technology: Birmingham College of Technology; Bradford Institute of Technology; Battersea College of Technology; Chelsea College of Science and Technology; Northampton College of Advanced Technology; Loughborough College of Technology; Salford Royal Technical College, and the Welsh College of Advanced Technology, Cardiff. Those approved as regional colleges are: Brighton Technical College; Bristol College of Technology; Brunel College of Technology, Acton; City of Liverpool College of Building and City of Liverpool College of Technology; Glamorgan College of Technology, Treforest; Huddersfield College of Technology; Kingston-upon-Thames Technical College; Leicester College of Technology and Commerce; North Staffordshire Technical College, Stoke-upon-Trent; Nottingham and District Technical College; Plymouth and Devonport Technical College; Portsmouth College of Technology; Rugby College of Technology and Arts; Sunderland Technical College; West Ham College of Technology; and in London, the Borough Polytechnic, Southwark; Brixton L.C.C. School of Building, Lambeth; Northern Polytechnic, Islington; Sir John Cass College; The Polytechnic, St. Marylebone, and Woolwich Polytechnic.

Imperial Cancer Research Fund

The fifty-fifth annual report of the Imperial Cancer Research Fund for 1956–57 (pp. 45. London: Imperial Cancer Research Fund, 1958), besides its survey of current work, refers to the approval of plans to build in Lincoln's Inn Fields, London, new and adequate laboratories adjoining the Royal College of Surgeons. The initial building costs are estimated at £600,000, and about £250,000 will be required for furnishing and equipping the laboratories, with an additional annual £150,000 for maintenance. The new research laboratories will provide accommodation for the chemico-pathological research at present being carried out at No. 48 Lincoln's Inn Fields, but will also permit a big expansion in the research programme of the Fund. Current work at Lincoln's Inn Fields is concerned mainly with the relation between hormones and human cancer, concentrating on cancer of the breast and of the prostate. An important part of the service there is the work on the early diagnosis of cancer by the study of smears of secretions. At the Mill Hill Laboratories fundamental biological research is largely concerned with tumour growth in animals and the characteristics of various malignant tumours. Dr. J. Craigie has perfected a method for storing tumours in a frozen state at – 32° C. for four to seven years, and human tumours, removed at operations or at post-mortem examinations, are being transplanted into laboratory animals so that the effect of different agents on cell growth can be observed. The reaction of tumour cells to changes in environment is being studied with an ingenious kinemicroscope with 'Perspex' observation chambers. Lists of papers published from the Laboratories since the last annual report are included in Dr. Craigie's and Prof. G. Hadfield's reports on the work of the Laboratories.

Soviet Crystallographic Meeting

The sixth general meeting called by the Commission for X-ray Diffraction of the Academy of Sciences of the U.S.S.R. was held in Leningrad during June 23–29. Some 900 people, including ten foreign guests, attended the opening session, which was addressed by the chairman of the Commission, Prof. G. S. Zhdanov (Moscow). The meeting proceeded in seven sections devoted to the X-ray study of alloys; X-ray studies of deformed metals; X-ray structural analysis and crystal chemistry; apparatus and methods of X-ray structural analysis; X-ray spectroscopy; electronography; and X-ray and γ-ray defectoscopy. The total number of papers contributed in these specialized sections was 333, and in addition there were twelve contributions during the full sessions. The rapid growth of crystallographic research in the Soviet Union is evident from this meeting, and from the reported production of sealed X-ray tubes in the U.S.S.R., namely, 3,887 tubes in 1957 and 4,700 in 1958. After the meeting most of the foreign guests travelled to Moscow and had opportunities of seeing the crystallographic work in progress in various institutes.

Travelling Fellowship and Student Prizes in Psychiatry

Mr. J. A. Baldwin, a medical student at the University of Aberdeen, has recently been awarded the first of the Mental Health Research Fund Travelling Fellowships. These are awarded annually to medical students, selected by an essay competition and interview, by the Mental Health Research Fund (39 Queen Anne Street, London, W.1), for special training in psychiatric or other departments abroad for six months. The Fund hopes in this way to stimulate interest in mental health and, particularly, in research bearing upon it, at an early stage in the student's career. The subject of the essay was "The Relative Importance of Nature and Nurture in the Development of Psychiatric Disorder". In addition to the Travelling Fellowship, three cash prizes have been awarded: £100 to Dr. G. Sedman, Manchester Victoria Memorial Jewish Hospital; £50 to Mr. J. D. Swales, Westminster Medical School; and £25 to Mr. A. P. K. John, Pembroke College, Oxford.

Institution of Civil Engineers

The following were recently elected to office in the Institution of Civil Engineers: *President*, Prof. A. J. S. Pippard; *Vice-Presidents*, A. C. Hartley, Sir Herbert Manzoni, Sir George McNaughton, R. W. Mountain; *New Members of Council*, L. Carnie (Glasgow and West of Scotland), N. S. Cox (South Western), A. Dean, S. E. Faber (Colonies), J. R. Farquharson (Colonies), J. T. D. Firth (North Western), O. Holden (Canada), W. P. F. McLaren (South Africa), T. P. de S. Munasinghe (Ceylon), R. H. Roberts (Northern and Southern Rhodesia), J. F. Stanbury, R. W. Taylor (Colonies).

University News: The Queen's University, Belfast

The following appointments have recently been made in the Queen's University of Belfast: Dr. G. Seth, to the chair of psychology; Dr. H. G. Heal, to a lectureship in inorganic chemistry; Mr. T. K. Marshall, to a lectureship in pathology (forensic medicine).

Birmingham

The following appointments in the University of Birmingham have recently been announced: Prof. D. L. Linton, professor of geography in the University of Sheffield, to the chair of geography, made vacant by the retirement of Prof. R. H. Kinvig, from October 1; Dr. P. J. Hilton, senior lecturer in mathematics in the University of Manchester, to the Mason chair of pure mathematics, made vacant by the resignation of Prof. C. A. Rogers, from October 1; Mr. I. T. S. Essery, to be senior lecturer in civil engineering; Mr. D. M. G. Wishart, to be lecturer in statistics in the Department of Pure Mathematics; Dr. J. D. Young, to be lecturer in physics; Drs. K. J. Morgan, R. S. Lehrle and J. D. Hobson, to be lecturers in chemistry; Dr. R. E. Smallman, to be lecturer in physical metallurgy; Mr. G. R. Coope, to be lecturer in geology; and Mr. N. Dennis, to be lecturer in sociology. The title of reader in mathematical physics has been conferred on Dr. G. E. Brown, lecturer in mathematical physics, from October 1.

Bristol

The following appointments in the University of Bristol have recently been announced: Mr. J. M. Cook, reader in classical archæology in the University, to a chair of ancient history and classical archæology; Dr. J. W. F. McOmie, to a readership in organic chemistry; Mr. R. W. Marsh, to a readership in plant pathology; Dr. Suzanne K. R. Clarke, to a lectureship in bacteriology.

London

The title of professor of pure mathematics in the University of London has been conferred on Dr. K. A. Hirsch, and that of professor of zoology on Dr. G. E. Newell, in respect of their posts at Queen Mary College. The following University appointments have also been made: Mr. A. Stuart, to the readership in statistics tenable at the London School of Economics and Political Science; and Dr. E. Cotchin, to the readership in veterinary pathology at the Royal Veterinary College.

Announcements

The Société Mycologique de France and the British Mycological Society are holding a joint foray at Reading during September 3–10. Further information can be obtained from Dr. F. B. Hora, The University, Reading, Berks.

A symposium on "Salinity Problems in the Arid Zones", organized by Unesco, will be held in Teheran during October 11–15. Further information can be obtained from M. Batisse, Arid Zone Unit, Department of Natural Sciences, Unesco, 19 Avenue Kléber, Paris XVI^{e}.

The annual conference of Aslib will be held at the University of Nottingham during September 5–8. Members are requested to register not later than August 22. Further information can be obtained from Aslib, 3 Belgrave Square, London, S.W.1.

The Institute of Rural Life at Home and Overseas is holding a course of rural studies at the Essex Institute of Agriculture, Writtle, near Chelmsford, Essex, during August 31–September 13. Further information can be obtained from the Institute, 159 Bryanston Street, Marble Arch, London, W.1.

The inaugural general meeting of the Gas Chromatography Discussion Group and an informal symposium will be held in the Chemistry Department, University College, Gower Street, London, W.C.1, on September 23. Further information can be obtained from Dr. D. Ambrose, Chemical Research Laboratory, D.S.I.R., Teddington, Middlesex.

A general discussion on "Ions of the Transition Elements", organized by the Faraday Society, will be held in Dublin during September 9–11. There will be two sessions, devoted respectively to optical and magnetic properties, and to the energetics of complexes. It is hoped to circulate advance proofs of the papers to be read. Further information can be obtained from the Assistant Secretary, Faraday Society, 6 Gray's Inn Square, London, W.C.1.

The twenty-seventh general meeting of the Society for General Microbiology will be held in the University of Liverpool on September 18 and 19. Those wishing to present papers, films or demonstrations should send the titles to Dr. B. W. Lacey not later than July 28. An informal meeting of those interested in animal viruses will be held on September 18. Further information can be obtained from Dr. B. W. Lacey, Department of Bacteriology, Westminster Medical School, London, S.W.1.

A Summer School, organized by the Universities Federation for Animal Welfare, is to be held at Culham College, Abingdon, Berkshire, during September 13–20. The programme will include lectures on various aspects of animal welfare, animal husbandry, humane technique in the laboratory, and related international problems. The fee, including full board, is £7, with a special reduced fee of £4 for students. All inquiries and applications to attend should be addressed to Miss M. P. Williams, Universities Federation for Animal Welfare, 7*a* Lamb's Conduit Passage, London, W.C.1.

SPECTROSCOPY OF SOLIDS

A CONFERENCE on the Spectroscopy of Solids, held by the Physical Society at the Royal Radar Establishment, Malvern, on May 28 and 29, brought together physicists from many parts of the world engaged in research in this field. Within the past two years, high-resolution infra-red spectroscopy has given a great deal of new information on various processes which lead to optical excitation of electrons from the valence to the conduction band in semi-conductors, and this in turn has led to a better knowledge of the band structure of silicon and germanium and also of a few of the intermetallic semi-conductors. In the opening paper of the conference, R. A. Smith discussed the various types of transition which take place in silicon and germanium, and, in particular, the part played by emission and absorption of phonons. The formation of exciton states was also discussed. These may be associated both with direct transitions in which the crystal momentum does not change, and in which no phonons are involved, and also with indirect transitions involving an appreciable change in crystal momentum and hence the emission or absorption of a phonon. Excitons associated with direct transitions give rise to a line absorption spectrum and those associated with indirect transitions to a band spectrum. Absorption due to both types of exciton formation was reported and discussed (see below).

High-resolution absorption spectra corresponding to indirect transitions in germanium, and obtained for a wide range of temperatures extending from 4° K., have previously been obtained for germanium by G. G. Macfarlane, T. P. McLean, J. E. Quarrington and V. Roberts, of the Royal Radar Establishment, showing absorption due to exciton formation. From these spectra, energies of the longitudinal and transverse acoustic phonons corresponding to the zone-edge in the $< 111 >$ directions, at which the minima in the conduction band occur, were obtained. These were found to be in good agreement with values obtained by B. N. Brockhouse and K. Iyengar from observations of neutron scattering. Similar measurements for silicon were now reported. From an analysis of these, the phonon energies for momentum values corresponding to the minima in the conduction band in the $< 100 >$ directions were obtained. Four types of phonon were observed having energies $k\theta$ with $\theta = 212°$, 670°, 1,050° and 1,420° K. These were interpreted as corresponding, respectively, to the transverse acoustic, longitudinal acoustic, longitudinal optical and transverse optical phonons. The fact that four phonons are observed and not three shows conclusively that the minima in the conduction band for silicon do not lie at the zone-edge as for germanium, since at the zone-edge the longitudinal acoustic and optical phonons have the same energy in the $< 100 >$ directions. It is estimated that for silicon the minima occur for a crystal momentum of about 0·8 times the value at the zone-edge. Accurate values for the forbidden energy gap in silicon, and for its variation with temperature, were also obtained from these measurements.

Fine structure in the recombination radiation of silicon was reported in a paper by J. R. Haynes, M. Lax and W. Flood, of the Bell Telephone Laboratories. This radiation was shown to be due to indirect transitions, and those corresponding to emission and absorption of all the four phonons discussed above were identified. Moreover, the phonon energies obtained in this way agree quite well with those obtained from the absorption spectra.

New measurements of the absorption due to the direct transition in germanium were also reported by Macfarlane, McLean, Quarrington and Roberts. These showed a strong line absorption due to the lowest exciton state. Owing to the effect of the Coulomb interaction between the free electron and hole, the form of the spectrum in the region of continuous absorption is considerably modified, and the variation with quantum energy $h\nu$ is not proportional to $(h\nu - \Delta E_0)^{\frac{1}{2}}$, as is frequently stated (ΔE_0 is the forbidden energy gap at the centre of the first Brillouin zone). The form of the continuous absorption spectrum was measured at high resolution and shown to be in very good agreement with that found theoretically on taking the Coulomb interaction of the free electron and hole into account. An accurate value for ΔE_0 is also obtained by this means.

In a theoretical paper on the phonon spectrum of germanium by F. Herman, of the Radio Corporation of America Laboratories, Princeton, forces including the effects of up to fifth nearest neighbours were taken into account. A comparison was made with the most recent observations by Brockhouse and Iyengar, using neutron scattering, of all four branches of the phonon spectrum of germanium.

The effect of strong magnetic fields on the absorption spectrum of germanium and other semi-conductors was described in papers by B. Lax and by S. Zwerdling, of the Lincoln Laboratory, Massachusetts Institute of Technology. Observation of the oscillatory magneto-absorption effect for direct transitions, due to quantization of electrons and holes into Landau levels in the magnetic field, previously reported by these authors, has been extended by use of higher spectral resolution to give the fine structure due to the degeneracy of the valence band of germanium. These observations enable the effective electron mass at the centre of the Brillouin zone to be determined. Magneto-absorption has now also been observed due to the indirect transitions involving emission and absorption of phonons. Observation of absorption in the direct transitions due to exciton formation was also reported; there was some indication of an excited state of the exciton. The variation of the position of the exciton absorption with magnetic field has also been studied.

Infra-red absorption due to impurities in semi-conductors was discussed by E. Burstein, of the Naval Research Laboratory, Washington. Recent observations have shown that the excited states of impurities in p-type silicon do not give a hydrogen-like spectrum. This effect is due to the degeneracy of the valence band at the centre of the Brillouin zone. The same author also discussed absorption spectra due to lattice vibrations in polar and homopolar crystals. New observations, with increased resolution, of the lattice absorption spectra of silicon were reported by F. A. Johnson, of the Royal Radar Establishment. It is now possible to interpret many of the absorption bands in terms of the phonon energies obtained from the indirect inter-band transitions. In most cases, two phonons are involved, but some of the weaker bands require three.

The optical properties of metals were discussed by F. Abeles, of the Institut d'Optique, Paris. Infra-red reflexion spectra have been studied with the view of obtaining information on the effective number of free electrons. Such observations for some of the noble metals and also for the alkali metals were discussed by M. H. Cohen, Cavendish Laboratory, Cambridge, who distinguished between thermal and optical effective masses and showed how the optical data may be used to determine whether the Fermi surface does or does not meet the boundaries of the first Brillouin zone.

Papers on a number of other materials were also presented, including diamond, quartz, and the compounds, InSb, CdTe and Bi_2Te_3. These were mainly concerned with observation of absorption and emission spectra. Such spectra have not yet been obtained with the same high resolution, or analysed in the same detail, as for silicon and germanium.

The conference was chosen as the occasion for the delivery of the forty-second Guthrie Lecture of the Physical Society, by Prof. W. E. Lamb, of the Clarendon Laboratory, Oxford, on "Experimental Tests of Quantum Electrodynamics".

During the conference an opportunity was available for delegates to visit the new Solid State Physics Laboratory at the Royal Radar Establishment. This was officially opened on the previous day, May 27, by the Right Hon. Aubrey Jones, Minister of Supply, together with a new laboratory for the study of guided missiles. The latter will be part of the laboratory facilities of the Guided Weapons Department under Dr. W. H. Penley. The Solid State Physics Laboratory will be included in the Physics Department under Dr. R. A. Smith. This Laboratory has been specially planned for research in the physics of solids and particular care has been taken to ensure very clean conditions. Complete air conditioning is not used throughout the Laboratory, but only in certain sections which are allocated to work in which minute quantities of certain impurities can have disastrous effects on experimental work. The new building also includes a small radiochemical laboratory and fairly extensive facilities for work at liquid-helium and liquid-hydrogen temperatures. Typical examples of the research work already beginning in the new building were demonstrated to those attending the conference. R. A. SMITH

THE DIPLOMA IN TECHNOLOGY

MANY who are concerned with the relation of science to industry combine to welcome, as a great educational reform, the institution of courses for the new Diploma in Technology. Candidature is open to science students who have obtained the General Certificate of Education (Advanced Level) or a good Ordinary National Certificate. The courses are mainly held in the top dozen or so colleges of technology, and often on a residential basis. Thus, students from Kent, Cornwall and Cumberland often study together, as at Brunel College, London, and elsewhere.

But obviously, the institution of a number of quite new degree-level courses, in different subjects, takes a good deal of working out, and raises many educational and administrative problems. In order to thrash these out further, the Brunel Staff Association held a national conference on June 20, attended by 180 delegates, being mainly senior members from the colleges concerned. Delegates were welcomed by Dr. J. Topping, principal of the College and himself a member of the National Council for Technological Awards, and by Mr. L. H. Hancock and Mr. E. E. Robinson, the conference chairman and secretary.

The opening paper, by Dr. A. J. Richmond, of the Welsh College of Advanced Technology, Cardiff, outlined the history of this great new educational venture; and the second paper, by Mr. Gordon Smith, of Brunel College, dealt with the industrial training period. While university education is all very well, it often neglects much which the young industrial scientist needs. Consequently, it was decided in 1955 to institute these new four-year courses, and on the sandwich principle. Thus, each student spends alternate periods of six months (*a*) at college and (*b*) undergoing industrial training in approved firms. Many companies now cordially welcome the scheme. Already a large proportion of the sandwich students are industry-based, that is, paid by their firms throughout the year. But the courses are open equally to students direct from a sixth form, with two advanced level and three ordinary level passes in General Certificate of Education examinations. These receive local education authority awards. More than 700 first-year students enrolled during the present session, and more than 1,000 are expected in 1958–59. The Diploma in Technology has already been recognized as the equivalent of a degree by the Burnham Committee.

Several speakers stressed the overloaded nature of many traditional science courses, where the student is expected to memorize far too many points of detail. A more selective, rather than an encyclopædic, approach is required. This comment was heard from as far apart as Mr. T. E. Hall, of Liverpool, with regard to building and civil engineering, and from Dr. E. G. Cowley, of Brighton, with regard to chemistry at both college- and school-level. It is one of the great potential virtues of the Diploma in Technology courses that syllabuses can be completely re-designed from first principles, to cope with this among other points. Mr. H. S. Barlow, of South-East Essex Technical College, however, questioned whether all colleges were seizing these exciting new educational opportunities boldly enough.

Modern methods of teaching and examining were also discussed, together with the general liberalization of approach. It was noted that those who qualify after the four years with a Diploma in Technology will be as useful to their firms as the average graduate is after another year or two of industrial training.

Further particulars about the courses are available from the Secretary, National Council for Technological Awards, 9 Cavendish Square, London, W.1.

NEW NATURE RESERVES IN ENGLAND

THE Nature Conservancy has announced the establishment of five new nature reserves in England, at Hickling Broad, Norfolk ; Bure Marshes, Norfolk ; Thetford Heath, Suffolk ; Weeting Heath, Norfolk ; and Knocking Hoe, Bedfordshire.

Hickling Broad comprises about 700 acres of shallow water surrounded by extensive reed-beds, fen, alder-wood and grass marshes characteristic of the Norfolk Broads. The history of the Broad as a bird sanctuary goes back to about 1911, when the late Lord Lucas, having bought the Whiteslea half of the Broad, approached a Hampshire friend and neighbour, Col. J. D. Mills (father of the present owner), of the Hickling half, who willingly agreed to let his part of it to form the sanctuary. Jim Vincent was appointed keeper. After the death of Lord Lucas, the ownership of one half and the lease of the other passed to the late Lord Desborough, who maintained the sanctuary at considerable personal expense with Jim Vincent's invaluable help.

The newly created National Nature Reserve, which lies 10 miles north-west of Great Yarmouth and covers an area of about 1,204 acres, has been established under Nature Reserve agreements with the owners, the Norfolk Naturalists' Trust and Major J. M. Mills.

The aquatic plant *Naias marina*, found in Britain only in certain Broads, is abundant at Hickling, together with many other rare plants, which are found in the marsh communities. The rich flora also supports some notable insects, of which the most outstanding is the swallowtail butterfly. The bittern, which re-established itself as a British breeding species on the nearby Sutton Broad in 1911, has bred at Hickling again since 1912, and the marsh harrier, which was also virtually extinct as a breeding species, returned rather later. To-day, harriers, bearded tits and bitterns are flourishing, together with several species of ducks, waders and other interesting birds.

The coypu, a large South American rodent which is now widespread in the Broads area, was first recorded at Hickling in 1950. It eats large quantities of vegetation and has in places eliminated much of the lesser reedmace. The increase of open water by eating out and breaking up encroaching plant life seems, on balance, so far to have been beneficial.

Those accustomed to visit the area will find no change as regards access, and the declaration as a reserve will not in any way affect the use of the Broad for sailing and fishing. Applications to visit the adjoining sanctuary area and for permits to collect specimens of plants and animals should be sent to the Secretary, Norfolk Naturalists' Trust, The Assembly House, Theatre Street, Norwich. Inquiries regarding proposed researches should be addressed to the Regional Officer for East Anglia, The Nature Conservancy, Government Offices, Bishopgate, Norwich.

The problem of the evolution and future of the Norfolk Broads is of considerable scientific and economic interest. Recent research has shown that many Broads were man-made in the Middle Ages and has partly explained why so many have become unnavigable lately. The Nature Conservancy has been asked to make a long-term scientific investigation of this problem, but as, unfortunately, no money could be found for it a start has not yet been possible. In addition to money and specialist staff, experimental areas are essential on which the scientists can work. These have now been provided through the generous co-operation of the Norfolk Naturalists' Trust and Col. Harry Cator and Mr. John Cator, of Woodbastwick, who have entered into Nature Reserve agreements on 734 acres of marshes and small broads (stretching some 2 miles from Ranworth to Decoy Broad, on the right bank of the Bure), which now comprise the Bure Marshes Nature Reserve.

Ranworth and Cockshoot Broads were given in 1949 by Col. Cator to the Norfolk Naturalists' Trust, who, with the support of the Conservancy, will continue to manage these Broads and marshes. Management of the privately owned Woodbastwick area also remains in the hands of its owners, and there will be no change as regards use or access.

The Breckland of south-west Norfolk and north-west Suffolk is an area of sandy heaths of the greatest importance for research on plant and animal populations in arid conditions resulting from its semi-continental climate and conjunction of sandy and chalk soils. Agricultural reclamation, afforestation, defence needs and other development have made great inroads into the unspoilt Breckland during the past thirty years. Thetford Heath, Suffolk, which lies 2½ miles south-west of Thetford and covers 225 acres, has been protected by the Norfolk Naturalists' Trust since 1949, and this reserve is now being declared under an agreement with the Trust.

Breckland birds in special need of conservation are well represented, and the breeding species include stone curlew, woodlark, wheatear and ringed plover. Most of the typical Breckland plants are to be found on Thetford Heath, which has, however, a stony broken ground surface with an incomplete covering of vegetation over a considerable area. During the 1930's parallel stripes of heather were observed, but it was not until recent years that this was connected with collections of flints in long parallel lines—the stone stripes revealed after the removal of a small area of surface soil during the Second World War.

Applications to visit and for authority to collect specimens of animals and plants should be made to the Regional Officer for East Anglia, The Nature Conservancy, Bishopgate, Norwich.

Weeting Heath, Norfolk, which has a wide range of Breckland heath vegetation types and consequently a flora and fauna of considerable interest, was purchased and presented to the Norfolk Naturalists' Trust in 1941, and a further area was added in 1944. Weeting Heath lies west of Brandon and covers 338 acres.

Typical Breckland birds, such as stone curlews, woodlarks, wheatears and a few pairs of ringed plovers (which rarely breed so far inland), are to be found. In the mid-section there is a wide area of bracken, and the reserve is separated from afforested land on the west by a well-defined stretch of ancient earthworks known as the Devil's Dyke. The absence of the rabbit from Weeting during the past two years has enabled uncommon plants to flower which had not been recorded there for many years. The northern section of Weeting Heath consists largely of chalky grassland forming a thick turf with pine trees scattered in groups. The more barren parts of the heath have yielded a very rare spider (*Oxyptila scabricula*), and another spider (*Philodromus collinus*) occurs only at two other places in Britain.

Applications for permits, which will be necessary for those who wish to visit the reserve, to undertake research and to collect specimens of animals or plants, should be addressed to the Regional Officer for East Anglia, The Nature Conservancy, Bishopgate, Norwich.

Knocking Hoe in Bedfordshire is a small relic of a particular type of close-grazed chalk downland turf, which is rapidly disappearing under the present system of land use in Britain. The turf is thought to be of very ancient origin, and has probably remained undisturbed by cultivation at least throughout historic times. There is a rich flora of low-growing chalk downland species. The reserve has been established under a Nature Reserve agreement with the owner, Mr. L. T. Franklin. It will continue to be used for sheep grazing, as this is considered to be the best way to preserve the present composition of the sward. Access to the reserve will be by permit only, of which only a very limited number will be issued. Applications can be made to the Regional Officer for the South-East, The Nature Conservancy, 19 Belgrave Square, London, S.W.1.

POPULATION STUDIES OF THE COMMON EARWIG

DURING the summer of 1956, there was a plague of the common earwig (*Forficula auricularia* Linn.) in the garden of 28 Yarborough Road, Lincoln. Traps were erected to catch the earwigs and large numbers were caught. P. F. Baker (*Trans. Lincolnshire Naturalists Union*, 14, No. 2; December 1957) made a study of the relative numbers of males and females in the population and of the percentage of the population consisting of the variety with large elliptical forceps, known as form *forcipata* Steph. Later, it was decided to investigate the distance moved by different individuals in the population; this was done by a marking experiment.

The final total of 337 males and 332 females showed that during August and September 1956, in the earwig colony studied, males and females were present in almost equal numbers.

The males were found to be the most variable: the commonest varieties being those in which one-half of the calipers differed markedly in curvature from the other. This was found in both typical and form *forcipata* males. Two specimens were caught which from their external appearance seemed to be gynandromorphs.

Previous work on population statistics had led to the belief that earwigs were migrating from one part of the garden to another and it was decided to assess the movements of separate individuals in the population. To investigate movement an evenly spaced network of traps was set up over the area so that each trap was about one yard from its immediate neighbours. Separate pots were labelled and all insects caught in any particular pot were marked on the elytra with oil paints of a colour characteristic of the pot.

To mark the insects during a period of relative quiescence—from general observations the earwig seemed to be active at night and inactive, or nearly so, during the daylight hours—an actograph was used. This relied on a displacement of equilibrium as the insect moves in a cage; a mark is registered on a drum. In this way the earwig was shown to be entirely nocturnal, commencing activity at dusk and continuing to dawn. For this reason removal of the insects from the traps was carried out in the daytime; these earwigs were then marked with oil paint and released at the base of the trap in which they were caught. The marking, to be recognizable, usually lasted for one retrapping only; other earwigs ate the oil paint off their fellows.

Recaptures of marked individuals made up 12 per cent of the whole.

The results showed small daily migrationary trends. In this case conditions were ideal and food was not scarce. It is known, however, that the common earwig will, under special environmental conditions or when food is scarce, migrate in thousands in search of new grounds.

DIRECTING YOUNG SALMON

RESEARCH on the methods of guiding young Pacific salmon while migrating downstream have recently been described by J. R. Brett and D. F. Alderdice (Fisheries Research Board of Canada. Bulletin No. 117: Research on Guiding Young Salmon at Two British Columbia Field Stations. Pp. viii+75. Ottawa: Queen's Printer, 1958. 75 cents).

The first experiments, in 1953, were performed in a large divided trough using captive sockeye yearlings. These tests were intended to survey broadly the possibilities of using various techniques, including light, sound, air bubbles, curtains of hanging chain, odours, dye releases and differences in water velocity as means of guiding young fish. Significant deflexion resulted from the use of a relatively large area of illumination at night, a band of rising air bubbles or bursts of dark dye during the day, and strands of chain hung vertically during both day and night.

Further trough experiments, in 1954, on the use of hanging chain demonstrated that the maximum distance between strands which produced a deflexion of 75 per cent or more fish through an angle of 45° was 4 in. Apart from its light-reflecting quality, the type of chain was found to be unimportant. The sensory stimulus causing the avoiding reaction was found to be primarily visual. Slow oscillation of the chain increased the deflexion of sockeye. Coho yearlings were not significantly deflected.

In conjunction with the trough experiments, a limited number of field tests using a 56-ft. oscillating chain deflector (144 oscillations a minute) in the

Lakelse River, British Columbia, proved that the technique had promise for guiding a natural run of young sockeye. At right angles to the direction of water flow a maximum of 79 per cent deflexion was achieved. However, the barrier was subject to considerable penetration if conditions were not ideal; coho were still not effectively deflected.

A number of modifications was introduced in the 1955 deflector. The chain was replaced by cables which were suspended from a continuous moving belt. The belt travelled across-stream, reversing at the entrance to the trap. Various intervals and rates of travel (to a maximum of 12 in./sec.) were tested. The combinations which proved most effective included an interval between strands of not more than 6 in., and rates of travel from 8 to 12 in./sec. In these circumstances an average of 92 per cent of sockeye and 59 per cent of coho were deflected.

In addition to changes in the deflector, a new opening or by-pass to the inclined-screen trap was built. The particular features of the by-pass were a reduction of visual cues in the entrance by using smooth, painted surfaces, a gradual acceleration of the incoming water to a velocity equal to or just exceeding the maximum swimming speed of the migrants, and the presence of cross-reflecting mirrors. Although the first model had limitations, it improved the trapping of deflected fish and permitted a good numerical assessment of the deflector.

The final tests were conducted in Hoolnose Creek during the spring of 1956. Pink, chum and coho fry, as well as sockeye and coho yearlings, migrate down this small stream. The same deflector was used, with additional features of smaller, weighted cables, a minimum interval of 2 in. between strands, low direct-current charging of the moving cables, and a 3-ft. wide sheet of metal on the stream bed, painted white to reflect light incident on the surface. The reduction in spacing was introduced to scale down the interval dimensions to a more appropriate size for fry. Also, by adding an electric charge, a combination of stimuli was presented which was thought would be more effective.

No success was obtained in guiding any of the fry. However, both coho and sockeye fingerlings were deflected at 95 per cent level and higher.

The investigations showed that new methods must be sought for the guiding of salmon fry. For yearlings, a full-scale test is desirable under conditions which approximate to reservoir characteristics of large dams.

A NEW APPROACH TO THE CHEMOTHERAPY OF CANCER

By Dr. M. B. SAHASRABUDHE

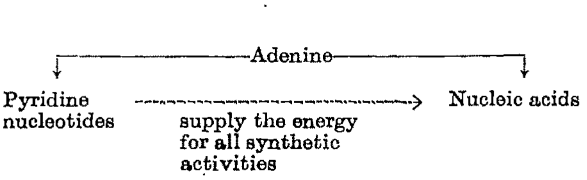
Biology Division, Atomic Energy Establishment, Trombay; Indian Cancer Research Centre, Parel, Bombay, India

THE use of antimetabolites as a means of controlling cancer was first investigated by Sidney Farber[1] in 1948, using folic acid antagonists. Since then a number of compounds having antagonistic properties against such essential metabolites as purines[2], pyrimidines[3], vitamins[4] and glucose[5] have been tested. The main drawback of the antimetabolites tested so far has been that they interfered with the normal processes also, and as such exhibited toxic effects. Further, some of the tumours develop resistance to the drugs. The former difficulty might be overcome by using antimetabolites against a specific substance or substances having an important function in tumours only; but in spite of the large amount of work, such a qualitative difference between a tumour and normal tissue has not so far been discovered. There are, however, quantitative differences which might be exploited with advantage in the chemotherapy of cancer.

One of the striking differences between normal and malignant tissues is the active cell proliferation accompanied by high rate of synthesis of nucleic acid in neoplastic tissues. This high rate, however, is not a characteristic solely of neoplastic growth. Normal embryonic tissues are also known to exhibit active nucleic acid synthesis without any evidence of neoplastic transformations. Hence embryonic and tumour tissues are similar in so far as active cell proliferation and nucleic acid synthesis are concerned; but whereas embryonic growth comes to a stop after a while, the tumour continues to grow apparently without any control whatsoever. In the present communication an attempt is made to explain these differences in the light of existing knowledge, and to suggest ways and means of exploiting these differences to control cancer growth.

Regulation of Normal Growth by Biological Feed-Back Mechanism

To maintain the rapid rate of synthesis of nucleic acid, two things are essential: (i) a continuous flow of precursors and (ii) an unrestricted supply of energy. In the biological system, the energy is usually generated in the Krebs tricarboxylic acid cycle through the stepwise degradation of metabolites into carbon dioxide and water. Pyridine nucleotides have an important role in this connexion in the hydrogen transport system, and thus indirectly participate in the energy production via the tricarboxylic acid cycle. One of the precursors of pyridine nucleotides is adenine, which is also a precursor of nucleic acids. Since the same substance (adenine) is required for the synthesis of nucleic acid and also of pyridine nucleotide, a sort of chemical competition is set up between the two for appropriation of adenine.



In an actively growing tissue, unless larger amounts of adenine are made available from the metabolic pool, it (adenine) is likely to be used for the synthesis of nucleic acid and very little will be left for the synthesis of pyridine nucleotides. This seems to be corroborated by published work[6] on the levels of pyridine nucleotides in various tissues (see Table 1).

Table 1. TOTAL DIPHOSPHOPYRIDINE NUCLEOTIDES + REDUCED DIPHOSPHOPYRIDINE NUCLEOTIDE IN THE LIVER OF ADULT, EMBRYONIC, NEW-BORN AND HEPATECTOMIZED RATS
(Compiled after Jedeikin, Thomas and Weinhouse, ref. 6)

	Total DPN + DPNH	Percentage lowering in total pyridine nucleotides
Liver from adult rats	770 (731–819)	
Liver from 19–20 day fœtus	262	66
Liver of new born 1–3 hr. after birth	441	43
Liver of new born 1 day after birth	336	56
Liver of new born 7 days after birth	722	Values within normal range
Maternal liver of 19–20 days pregnant mother	550	28
Liver of mother 1 day post-partum	846	Values within normal range
Regenerated liver 3 days after hepatectomy	592	23
Hepatoma	250	78

Table 2. PYRIDINE NUCLEOTIDE LEVELS IN HOST TISSUES (μGM./GM. WET TISSUES) OF TUMOUR-BEARING ANIMALS: INFLUENCE OF NICOTINAMIDE ADMINISTRATION ON *in vivo* STIMULATION OF SYNTHESIS OF PYRIDINE NUCLEOTIDE
(Compiled after Narurkar, Kumta and Sahasrabudhe, ref. 7)

	Livers		Spleen		
	Control animals	Tumour-bearing animals	Control animals	Tumour-bearing animals	Tumour (fibro-sarcoma)
Initial	671	561	456	337	119
Levels of pyridine nucleotide after administration of 500 mgm./kgm. body wt. nicotinamide	3,063	1,334	2,900	892	611
Net synthesis of pyridine nucleotide in 12 hr.	2,393	773	2,444	535	492

It will be seen from Table 1 that active proliferation is invariably accompanied by lowering of the pyridine nucleotide levels. The figures for livers of mothers 19–20 days pregnant suggest that not only the adenine present in the fœtus is channelized for nucleic acid synthesis, but even that present in the metabolic pool of the mother is also drained, resulting in the depletion of pyridine nucleotide levels in the maternal livers of pregnant animals.

Sahasrabudhe and co-workers[7] have recently demonstrated that the pyridine nucleotide levels in the host tissues of tumour-bearing animals are considerably lower. Nicotinamide ribotide and adenine ribotide combine by a pyrophosphate bond to form a pyridine nucleotide molecule: nicotinamide–ribose–P–P–ribose–adenine. Kaplan[8] has shown that when nicotinamide is administered, pyridine nucleotide synthesis can be artificially boosted. The levels of pyridine nucleotide synthesized, however, will be determined by the availability of adenine from the metabolic pool for the synthesis of pyridine nucleotide. Sahasrabudhe and co-workers[7] attempted to stimulate the *in vivo* synthesis of pyridine nucleotide by injecting 500 mgm./kgm. body-weight of nicotinamide. The livers and spleens of normal non-tumour-bearing animals showed a net synthesis of 2,393 and 2,444 μgm. of pyridine nucleotide. The net synthesis in the liver, spleen and tumour of tumour-bearing animals, however, was only 773, 553 and 492 μgm.; that is, less than a third of that in tissues of normal animals (Table 2). This clearly suggests the unavailability of adenine for the synthesis of pyridine nucleotide in tumour-bearing animals.

But this appropriation of adenine for nucleic acid synthesis and the depletion of pyridine nucleotide levels cannot go on indefinitely, because in absence of adequate levels of pyridine nucleotide, hydrogen transport and energy production cannot go on efficiently. Since nucleic acid synthesis requires energy, the appropriation of adenine will itself act as a self-regulatory feed-back mechanism by limiting the pyridine nucleotide levels. This, it is suggested, is the mechanism by which normal hyperplasia comes to a stop after a particular level of proliferation has been achieved. The fact that tumours continue to grow indefinitely, apparently without the self-regulating feed-back mechanism just described, suggests that the tumours find alternative ways of producing their own energy requirements, independent of pyridine nucleotide levels and the tricarboxylic acid cycle.

Run-Away Growth in Tumours: Tumour Autonomy in Energy Production

Until recently, the Embden–Meyerhof pathway was regarded as the sole prototype of glycolysis whereby glucose was metabolized through the formation of glucose-6-phosphate, fructose-6-phosphate, fructose-1-6-diphosphate and triose phosphate, etc., as shown in Fig. 1. It is only recently that growing evidence has been forthcoming through the researches of Warburg, Lipman and Dickens to suggest an alternative pathway of glycolysis known as the hexose–monophosphate shunt or oxidative pathway[9].

In the absence of adequate levels of pyridine nucleotide, as in actively growing tumour tissues, the operation of the tricarboxylic acid cycle and the production of adenosine triphosphate are impaired, which perhaps result in accumulation of lactic acid. In the hexose–monophosphate pathway, no adenosine triphosphate is required; instead, an obligatory oxidation occurs early in the reaction sequence. It has been shown that sedoheptulose-7-phosphate and erythrose-4-phosphate can either be converted to triose phosphate and thus meet the Embden–Meyerhof pathway, or these may alternatively be converted to fructose-6-phosphate and re-enter the hexose–monophosphate cyclic processes[9]. Repeated opera-

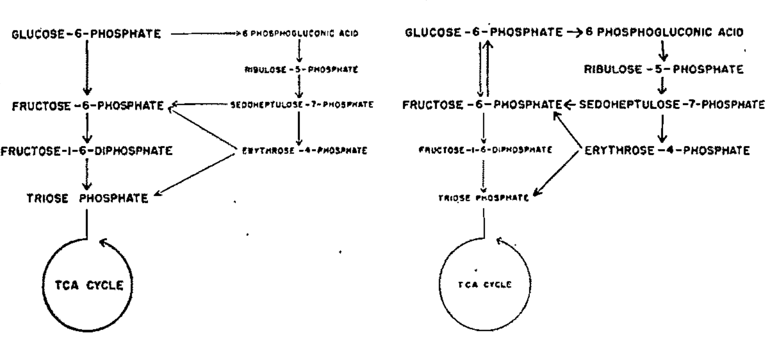


Fig. 1. Relative preponderance of Embden–Meyerhof and hexose-monophosphate pathways of glycolysis in normal and neoplastic tissues. Bold lettering and thick lines indicate the preponderance

tions of the hexose–monophosphate oxidative cycles yield carbon dioxide as the sole and final product, with the release of all the energy contained in the glucose molecule. How this energy is utilized is, however, not definitely known. It is perhaps a happy coincidence that the major portion of the ribose moiety, which is so essential for nucleic acid synthesis, is derived from the hexose–monophosphate pathway. It is felt that this is an example of efficient biological adaptation to get over the block in energy production and to get the most benefit with the least effort. Whatever be the correct explanation of this phenomenon, the cause and effect relationship appears to be very striking and calls for closer scrutiny. Whether any sustained and rapid synthesis of nucleic acid automatically accelerates the hexose–monophosphate pathway as an adaptive mechanism, or whether this is a characteristic of neoplastic transformations only, is at present under investigation and will be reported elsewhere.

Radioactive isotope technique has played a vital part in evaluating the relative rates at which the alternative pathways of glycolysis predominate in a given system. For this purpose samples of glucose labelled at the first or the sixth carbon atoms with carbon-14 have been used, and by determining the radioactivity in the carbon dioxide formed, one can evaluate the extent to which the two alternative glycolytic pathways are operative[10]. Using this technique, Van Vals, Bosch and Emmelot[11] have demonstrated the preponderance of the hexose–monophosphate oxidative pathway in a variety of tumours and their results are briefly summarized in Table 3.

Table 3. INCORPORATION OF RADIOACTIVITY IN CARBON DIOXIDE USING GLUCOSE-1-^{14}C AND GLUCOSE-6-^{14}C AS SUBSTRATES
(After Van Vals, Bosch and Emmelot, ref. 11)

	Ratio of *R*6/*R*1*	
	Without malonate	With malonate
Heart	1·05	0·42
Kidney	1·01	0·52
Brain	1·08	0·46
Spontaneous mammary carcinoma (*Dba*)	0·60	0·18
*T*5358 : interstitial cell carcinoma testis	0·51	0·13
*UV*256 sarcoma	0·58	0·02
*T*26567 sarcomatoid ovarian tumour	0·72	0·25

$$^{*}\frac{R6}{R1} = \frac{\text{Radioactive CO}_2\text{ liberated using glucose-6-}^{14}\text{C}}{\text{Radioactive CO}_2\text{ liberated using glucose-1-}^{14}\text{C}} = \frac{\text{(EM and TCA)}}{\text{(EM and TCA)} + \text{(HMP)}}$$

There is, however, one point which needs explanation. The two dehydrogenases in the early reaction sequence of the hexose–monophosphate pathway are dependent on the level of triphosphopyridine nucleotide. The question that naturally arises is how do these dehydrogenases function at higher levels when the levels of total pyridine nucleotide and triphosphopyridine nucleotide in particular are depleted. Glock and McLean[12] have examined this point closely and have found high values of dehydrogenase activity with low levels of triphosphopyridine nucleotide. Either it means that the tumour dehydrogenases are not dependent on triphosphopyridine nucleotide or that some other substance such as a specific dinucleotide acts as a hydrogen carrier in place of it.

Summarizing, therefore, it is suggested that the high rate of synthesis of nucleic acids in malignant transformations results in depletion of the levels of pyridine nucleotides and acceleration of the hexose–monophosphate pathway to obtain the energy required for proliferation. How low the level of pyridine nucleotides becomes will depend on how fast the synthesis of nucleic acid is going on. This concept of chemical competitions as the causative factor determining the levels of pyridine nucleotides, if true, might help in reconciling the divergent views held by Warburg[13] and Weinhouse[14] regarding the role of respiration in tumour tissue.

New Approach to Chemotherapy

It would appear from the foregoing discussion that the tumour derives its energy via the hexose–monophosphate pathway. It may be because of the independence of this pathway from normal regulatory feed-back mechanism that the tumour enjoys autonomy with regard to production of energy for its proliferation. Further, since the hexose–monophosphate pathway is not operative to a major extent in other normal tissues, any interference with that pathway might result in preferentially arresting the tumour growth only.

The possibilities and usefulness of preparing antimetabolites against glucose-6-phosphate, 6-phosphogluconic acid, ribulose-5-phosphate, etc., have therefore been considered. Since glucose-6-phosphate takes part in the Embden–Meyerhof as well as in the hexose–monophosphate pathway, use of its antimetabolites would exhibit toxic effects due to blockage of the Embden–Meyerhof pathway in normal tissues. Similarly, ribose is a constituent of a number of essential cofactors such as diphosphopyridine nucleotide, co-enzyme A, etc., which are necessary for normal body processes. Any substance, therefore, which interferes with ribose utilization would interfere with normal processes also and might prove toxic. Analogues of 6-phosphogluconic acid, however, appear to be free from any such objections. Work is at present in progress in this laboratory along these lines, and the preliminary results so far obtained with experimental chemotherapy of cancer with some of the compounds specially synthesized for the purpose are very encouraging. Details of this work will be published elsewhere.

DISTRIBUTION OF PELAGIC POLYCHÆTES IN THE SOUTH ATLANTIC OCEAN

By NORMAN TEBBLE

British Museum (Natural History)

IT has been established that the major hydrological boundaries in the South Atlantic Ocean restrict the distribution of many species of zooplankton[1]. Examination of pelagic polychætes collected by the "Discovery" Committee, between the ice edge (in 70° S.) and the equator, demonstrates for the first time that many of these have a significant distribution in relation to the sub-tropical and antarctic convergences. Minor hydrological boundaries affect the dispersal of particular populations and a correlation has been found to exist between the distribution of species and the movements of water masses.

Three pelagic polychætes do not occur north of the antarctic convergence and are endemic to the antarctic zone; they are *Rhynchonerella bongraini*, *Vanadis antarctica* and *Tomopteris carpenteri*. In the Atlantic sector *R. bongraini* has been found only in the top 500 m. of water in the antarctic zone within Weddell Sea water, the east wind drift, and in the upper layers of the warm deep water. *V. antarctica* probably occurs in all explored water masses in the antarctic zone; it is similar morphologically to *Vanadis longissima*, from farther north, and they may represent geographical races of one species. *Tomopteris carpenteri* was found, as adult, in all explored water masses of the antarctic zone; the smallest specimens of this species were, however, collected around South Georgia only, which suggests it may be a breeding area.

There seem to be no endemic sub-antarctic pelagic polychætes, *Vanadis longissima* being the only species (or geographical race of a species) with its southerly limit of distribution at the antarctic convergence; apart from occurring in the sub-antarctic zone it was collected only in the sub-tropical and tropical zones.

The following species have been found in the tropical and sub-tropical zones only; they appear to be limited in their southerly distribution by the sub-tropical convergence: *Tomopteris ligulata**, *T. krampi*, *T. elegans**, *T. apsteini**, *T. nisseni*, *Vanadis formosa**, *V. crystallina**, *Rhynchonerella angelini*, *Krohnia lepidota**, *Alciopa reynaudi**, *Naiades cantraini**, *Travisiopsis lobifera**, *T. lanceolata*, *Lopadorhynchus brevis**, *L. uncinatus**, and *L. krohni**.

It is noteworthy that twelve of these species (marked with an asterisk) are not known to occur in the North Atlantic Ocean to the north of the secondary polar front (as defined by Böhnecke[2]), which is a similar hydrological boundary to the sub-tropical convergence in the South Atlantic. These species appear to circulate in the Atlantic Ocean entirely between these boundaries.

The remaining species, *Tomopteris nisseni*, *T. krampi*, *Rhynchonerella angelini* and *Travisiopsis lanceolata*, range northward beyond the secondary polar front in the North Atlantic Ocean—in brief, this front is no barrier to them. No endemic pelagic polychætes are known from arctic waters, which implies that there is a constant influx of more southerly populations maintaining the homogeneity of the species over a wide area and preventing the evolution of endemic species. It is possible, therefore, that the endemic antarctic *Tomopteris carpenteri* may be represented in the arctic fauna by *T. nisseni* and *T. krampi*. Similarly, the endemic antarctic *Rhynchonerella bongraini* corresponds to *R. angelini*. Likewise, although the genus *Travisiopsis* is not represented by an endemic species in the antarctic zone, the species *T. coniceps* occurs only in southern waters and its corresponding species in arctic waters is *T. lanceolata*.

The following species were collected in all hydrological zones in the South Atlantic Ocean: *Tomopteris planktonis*, *T. septentrionalis*, *Typhloscolex mülleri*, *Travisiopsis levinseni* and *Pelagobia longicirrata*. Of these, *Tomopteris planktonis*, *T. septentrionalis* and *Travisiopsis levinseni* were collected in all explored water masses but never in regular abundance. *Typhloscolex mülleri* was collected in the antarctic zone in the warm deep water thoughout the year, migrating to depth in winter. A few records from the surface layers in summer suggest that at this season this species may also penetrate into Weddell Sea water. North of the antarctic convergence *T. mülleri* inhabits antarctic intermediate water, South Atlantic central water, and possibly also tropical surface water. *Pelagobia longicirrata* is the most abundant of all pelagic polychætes, and south of latitude 45° S. undergoes a migration to depth in winter. This species has been found in its greatest numbers in summer in the top 100 m. of water about the Greenwich meridian in the antarctic and sub-antarctic zones between the ice edge and 45° S. North of this latitude, to the sub-tropical convergence, it has not been found between 100 m. and the surface in samples so far examined. Böhnecke[2] has noted the presence of a boundary in this region which separates well-mixed water in the southern half of the sub-antarctic zone from more stably stratified water in the northern half; this boundary may segregate a southern population of *P. longicirrata* which inhabits these surface layers in summer (whether for feeding or for breeding purposes is not known). Elsewhere in the South Atlantic Ocean *P. longicirrata* has been collected in all explored water masses.

The distribution of species occurring at depth and limited in their range by surface hydrological boundaries may be explained by migration between water masses moving in opposite directions. Throughout the sub-tropical and tropical zones, species which do not occur south of the sub-tropical convergence could maintain their environment by migrating between southerly flowing South Atlantic central water, northerly flowing antarctic intermediate water and/or southerly flowing warm deep water. Surface currents throughout these zones set up an anti-clockwise circulation which would also restrict the southerly movement of the species.

It is probable that most cosmopolitan pelagic polychætes enter the antarctic and sub-antarctic zones in the southerly flowing warm deep water. By migrating upwards in the antarctic zone to antarctic surface water, and moving with this layer to its conversion into northerly flowing antarctic intermediate water, circulation throughout the South Atlantic would be maintained. Within the antarctic zone a closed circulation, between antarctic surface water and warm deep water, is the simplest explanation of zonal movement, but endemic antarctic species, and antarctic populations of cosmopolitan species, are undoubtedly affected by much more complex circumpolar influences.

A full account of this study will be published elsewhere.

RELATIONSHIP BETWEEN PHYTOALEXIN OUTPUT AND THE NUMBER OF INFECTIONS INVOLVED

By K. O. MÜLLER

Commonwealth Scientific and Industrial Research Organization, Division of Plant Industry, Canberra

As previously reported[1], the germ tubes of *Phytophthora infestans* readily penetrate the epidermis of the seed cavities of *Phaseolus vulgaris*. The result of such penetrations is seen as necrotic lesions involving usually only one or two host cells, but the pathogen simultaneously ceases to grow and spread.

It was later shown[2] that the pathogen is checked by the antibiotic factor, phytoalexin, which results after infection from an interaction between the host tissue and the pathogen. In an attempt to study the relationship between the number of germ tubes penetrating into the host cells and the output of phytoalexin, experiments using known concentrations of zoospore suspensions were carried out along the following lines.

The pod cavities were inoculated with known volumes of zoospore suspensions varying in concentration from 8×10^{2} to 10^{4} zoospores per cm.^{3}. After incubation for 24 hr. at 20° C., the droplets were collected and the solutions thus obtained were tested in serial dilution by bio-assay with *Sclerotinia fructicola*[2], for their antibiotic activity. The latter was assessed by determining that dilution at which the length of the germ tubes was fifty per cent of that of the control. The reciprocal of this dilution was taken as the measure of activity in the undiluted solution or of the number of phytoalexin units per mm.^{3} of that solution. By definition, unit activity results from 1 phytoalexin unit per mm.^{3}, and this concentration will reduce the growth of germ tubes to one-half in the standard assay technique.

The number of cells directly affected by the pathogen was determined by removing the inoculated epidermal layers from the treated cavities after the inoculation drops had been collected, and by placing them in a 10 p.p.m. rhodamine *B* solution. After 3 hr. these layers were examined microscopically. The invaded and one or more adjoining cells showed staining. The figures in Table 1 refer to the number of penetrations per mm.^{2} of inoculated area.

The results tabulated are the averages for four experiments. It can be seen that there is no correlation between the number of infections (or penetrations) and phytoalexin output per mm.^{2} of inoculated host tissue. Only when the suspension was so diluted as to reduce the number of zoospores per mm.^{2} to less than 1 was an effective decrease in phytoalexin activity recorded.

It is pertinent to calculate the theoretical output of phytoalexin per mm.^{3} of inoculated epidermal tissue, on the assumption that ultimately there is the same concentration of phytoalexin in the bulk diffusate as in the affected cells. The calculation is also based on the assumption that the whole of the cell volume participates in the production of phytoalexin, and that no phytoalexin is inactivated by zoospores in the bulk diffusate. Any appropriate corrections would, however, increase the theoretical concentration of phytoalexin. The result of such a calculation is shown in the second row of Table 1.

The third row in Table 1 gives the calculated output of phytoalexin per mm.^{3} of affected cells. These figures are extremely high when one considers that 5–6 units of phytoalexin per mm.^{3} of water will completely inhibit hyphal growth *in vitro*. Thus when there are 56 penetrations per mm.^{2} of epidermal tissue the output of phytoalexin is more than 350 times that necessary to inhibit completely hyphal

Table 1. NUMBER OF PENETRATIONS PER MM.^{2} OF INOCULATED AREA AND OUTPUT OF PHYTOALEXIN

	Number of infections/mm.^{2} inoculated area								
	56	27	18	12	7	3	3	2	0·5
(1) Phytoalexin concentration in activity units in bulk diffusate	5·0	4·3	6·7	5·0	5·0	5·0	2·4	3·4	< 0·5
(2) Phytoalexin act. units produced/mm.^{3} epidermal tissue*	237	202	315	237	237	237	113	160	< 23·5
(3) Phytoalexin act. units produced/mm.^{3} affected tissue*	$2·16 \times 10^{3}$	$3·85 \times 10^{3}$	$9·01 \times 10^{3}$	$1·01 \times 10^{4}$	$1·73 \times 10^{4}$	$4·04 \times 10^{4}$	$1·94 \times 10^{4}$	$4·12 \times 10^{4}$	$< 2·42 \times 10^{4}$

* Calculated from figures of row 1, in using the following data and formulæ:

Mean vol. liquid recovered from a single inoculated area = 9·2 mm.^{3}
Mean single epidermal area covered by the inoculum = 8·45 mm.^{2}
Mean depth of the epidermis = 23μ
Mean vol. of an individual epidermal cell = 28,100μ^{3}
Mean number of cells affected per point of penetration = 1·6

$$\text{Phytoalexin produced/mm.}^{3}\ \text{epidermal tissue inoculated} = \frac{\text{Phytoalexin conc.} \times 9·2}{8·45 \times 0·023}$$

$$\text{Phytoalexin produced/mm.}^{3}\ \text{tissue infected} = \frac{\text{Phytoalexin conc.} \times 9·2 \times 10^{9}}{\text{Infections/mm.}^{2} \times 8·45 \times 28{,}100 \times 1·6},$$

growth at the site of infection; when there are 2 penetrations per mm.^{2} the output of phytoalexin is some 7,000 times more than that necessary.

The conclusions that (1) the output of phytoalexin is excessively high per unit volume of affected cells, and (2) the output of phytoalexin is essentially constant per unit area of inoculated area suggest that not only the invaded cells but also the rest of the tissue adjacent to the inoculated face participates in the formation and liberation of phytoalexin. If so, it must be assumed that a factor diffuses into the inoculation drop which induces the non-infected cells to produce the inhibitory substance in their turn. In view of the fact that measurements of conductance in tissues interacting with the pathogen in a suprasensitive fashion showed evidence of effect in advance of the pathogen[3], the above suggestion need not be considered too speculative. Also, the recent findings of Millerd and Scott[4], who separated a chemical factor from barley leaves infected with *Erysiphe graminis* which increases the respiratory rate in uninfected leaves, fit in with this hypothesis.

STEREOCHEMISTRY OF COMPLEX HALIDES OF THE TRANSITION METALS

By Dr. NAIDA S. GILL, Prof. RONALD S. NYHOLM, F.R.S., and PETER PAULING

THE ligand (crystal) field theory, originally developed by Bethe[1] and Van Vleck[2], has been used extensively since 1951 for the interpretation of the spectra of transition metal complexes[3]. It had been employed earlier to explain the magnetic properties of compounds of the transition[4] and rare earth metals[5], and, more recently, those of the actinide metals[6]. It has also proved very valuable in providing an increased understanding of the stereochemistry of transition metal complexes[7,8].

The ligand field theory considers the effect of the electrostatic field due to the ligands on the energy of the non-bonding d-shell of the central metal atom and assumes that the arrangement of the ligands about the metal atom is determined primarily by this non-bonding d-shell. The successes of the ligand field theory suggest that in many molecules and complex ions the dominating energy terms are indeed those related to electrostatic effects on the inner non-bonding d-electrons. We wish to direct attention in this article to cases in which this is not true, and in doing so to delineate more precisely the value of ligand field and other theories in the prediction and interpretation of the stereochemistry of transition metal complexes. While recognizing the validity of the energy effects calculated by ligand field theory, we believe that other factors such as the stabilizing energy of the directed σ-bond, the principle of electroneutrality of the metal ion[9], the polarizability of the ligand, the possibility of π-bonding between metal and ligand and the steric effects which result from interaction between ligands, are potentially important as structure determinants. We suggest that sometimes these may overcome ligand field effects and give rise to co-ordination shapes different from those expected from simple ligand field theory. First, we regard the principle of electroneutrality as of major significance in deciding the co-ordination number of the metal ion, for a knowledge of this must precede discussion of stereochemistry. In general, the preferred co-ordination number of a metal ion increases with its valency, and Pauling[9] has suggested that, as a rough rule, the co-ordination number is twice the valency. It is well known, however, that two or more co-ordination numbers may occur for the same metal ion; for example, $[FeF_6]^{3-}$ and $[FeCl_4]^-$. We consider that this arises not so much from steric effects as from differences in the polarizability of the various ligands and consequent transfer of charge to the metal ion through the σ-bond. For example, Fe^{3+} takes up ligands until its effective charge is reduced to nearly zero; it will require a greater number of F^--ligands to achieve this than Cl^--ligands, because there is greater electron transfer from each Cl^- to Fe^{3+} than from each F^-. Another example of this is the comparison of $[Co(H_2O)_6]^{2+}$ with $[CoCl_4]^{2-}$; the co-ordination number decreases as we pass from the less easily polarized H_2O to the more readily polarized Cl^- ligand.

Before discussing the shapes of complexes of metals the atoms of which have a non-spherical electronic shell, it is helpful to summarize the shapes expected for ions which have perfect spherical symmetry. As discussed elsewhere[8], the stereochemistry of complexes of non-transition metals can be generalized in terms of repulsions between *bonds* (whether single, double or triple) and lone pairs of electrons in the valency shell. This follows the approach originally suggested by Sidgwick and Powell[10]. On this model, the shapes of CH_4, NH_3 and H_2O are all based upon the tetrahedral arrangement, there being a total of four (bonds + lone pairs) in each case. The steady fall in the $H - X - H$ angle in the above sequence is explained by assuming that the repulsion lone pair : lone pair > lone pair : bond pair > bond pair : bond pair[11]. One can extend this picture to those transition metals the non-bonding d-shells of which are spherically symmetrical, elements with configurations d^0, d^5 (spin-free) and d^{10}. For ions with these configurations the shapes of complex molecules having no lone pairs are expected to be linear, triangular planar, tetrahedral, trigonal bipyramidal, octahedral and pentagonal bipyramidal, according as the co-ordination number is 2, 3, 4, 5, 6 or 7.

To appreciate the stereochemistry of complex ions with other than 0, 5 or 10 non-bonding d-electrons, the shapes of d-orbitals and their effect on the arrangement of the ligands must be considered. The ligand field theory assumes a purely electrostatic model for the calculation of energy effects; for example, the ion $[CoCl_4]^{2-}$ is regarded as a Co^{2+} surrounded by four Cl^- at the corners of a regular tetrahedron. Referred to orthogonal axes, the five d-orbitals may be divided into two classes; one class, the d_γ-orbitals, have lobes of electron density along

Table 1. CRYSTAL FIELD STABILIZATION* AND STEREOCHEMISTRY EXPECTED ON LIGAND FIELD THEORY (ALL SPIN-FREE)

No. of *d*-electrons	0, 5 or 10	1 or 6	2 or 7	3 or 8	4 or 9

* $\Delta^1 = 4/9\ \Delta$

the *z*-axis (d_{z^2}) and along the *x*- and *y*-axes ($d_{x^2-y^2}$). The second class, d_ε orbitals, have their lobes of electron density in between the *x*-, *y*- and *z*-axes. There are three d_ε orbitals (d_{xy}, d_{xz} and d_{yz}) in the *xy*-, *xz*- and *yz*-planes, respectively. In an octahedral complex, these two classes of orbitals have different energies, the d_γ-doublet being of higher energy than the degenerate d_ε triplet. The lobes of electron density in the d_γ-orbitals point *towards* the ligands and in the d_ε-orbitals they point *between* the ligands. The separation Δ, or 10 Dq, between these degenerate levels is a measure of the strength of the electrical field produced by the ligands[3]. This is shown in Fig. 1*a*. For a tetrahedral complex the d_ε- and d_γ-levels are inverted since it is the d_ε orbitals which now point towards the ligands. The energy-levels are shown in Fig. 1*b*. In all cases the ligands are regarded as negative point charges.

When comparing complex ions of the same shape but having different numbers of *d*-electrons, this splitting leads to certain stabilization. Consider an octahedral complex of a d^1-ion, for example, Ti^{3+}. If the single *d*-electron were to spend 1/5 of its time in each of the five *d*-orbitals, its energy would be given by the point *A*. However, in fact, it is located in the d_ε-orbitals and the complex is more stable than the above hypothetical mean by an amount 4 Dq. This is the crystal field stabilization energy. For a tetrahedral complex, the value of Δ^1 is only 4/9 of Δ, and crystal field stabilization energies are consequently smaller for these complexes. Table 1 gives theoretical values for these crystal field stabilization energies.

We must take into account this effect in addition to the interactions between bonding pairs of electrons (σ-pairs) discussed earlier for spherically symmetrical metal ions. One expects to obtain a regular tetrahedron with the configurations d^0, d^2, d^5 (spin-free), d^7 (spin-free) and d^{10}, that is, when d_ε- and d_γ-shells in Fig. 1*b* are empty, half full or full. Tetragonal or square planar arrangements are expected for d^4 (spin-free) and d^9 configurations. Finally, all spin-free configurations except d^4 and d^9 should also give rise to a perfect or very slightly distorted octahedron. From ligand field theory the tetrahedral arrangement is expected to occur less frequently than the octahedral, since the crystal field stabilization energy is always larger in the latter case. These values are sometimes used as a means of assessing the relative ease of obtaining tetrahedral *vis-à-vis* octahedral complexes. However, we consider that there are so many other factors influencing the question that the value of crystal field stabilization energies for this purpose is limited.

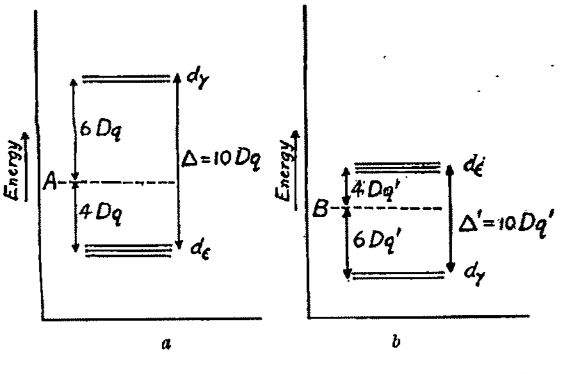

Fig. 1. Splitting of orbital levels in (*a*) octahedral complex; (*b*) tetrahedral complex, $\Delta^1 = 4/9\ \Delta$

We note that Orgel[3] has pointed out that, although crystal field splittings appear to be the important factors determining the relative stabilities of the tetrahedral and octahedral configurations, nevertheless these qualitative arguments may well prove deceptive; and he stressed the need for further testing of the theory.

First, even when using the purely electrostatic model, it needs to be emphasized that the energy required to assemble the field-producing arrangement is not the same. In other words, the positions *A* and *B* in Fig. 1 do not represent the same energy, and, indeed, the difference between these could be of even greater significance than the crystal field stabilization energy which is measured relative to these points. Secondly, these calculations ignore repulsions between ligands, and the fact that metal-ligand bond distances in octahedral and tetrahedral complexes are not usually the same.

The theory suggests that for electronic configurations other than d^0, d^2, d^5, d^7, d^{10} and also spin-paired d^4, a regular tetrahedral arrangement is much less probable than an octahedral, tetragonal or square planar one. Thus four-covalent spin-free Ni^{II} (d^8) and Fe^{II} (d^6) complexes are not expected to occur in a regular tetrahedral arrangement; but rather, if they occur at all, in a grossly distorted tetrahedron. There has long been speculation concerning the existence of tetrahedral Ni^{II} complexes. The usually accepted example, Ni^{II} *bis*-acetyl acetone[12,13], is now known to be a trimer almost certainly involving octahedrally co-ordinated nickel. Recently, however, Venanzi[14] has reported that complexes of the type $NiCl_2.2Ph_3P$ are monomeric in benzene, and hence the nickel atom is four-covalent; X-ray studies by Venanzi and Powell indicate that it is at the centre of a distorted tetrahedron[14]. This result is supported by the magnetic moment (3·1 B.M.), which is only slightly in excess of the spin-only value, 2·83 B.M., the orbital contribution being small. The latter should be large if the Ni^{II} is surrounded by a regular tetrahedron of negative charges. This arises because,

Table 2. ARSONIUM TETRACHLORO COMPLEXES OF TRANSITION METALS
General formula [Ph$_3$MeAs]$_2$[MCl$_4$]

Property	Metal					
	Mn^{II}	Fe^{II}	Co^{II}	Ni^{II}*	Cu^{II}	Zn^{II}
Colour	Pale green	Cream	Blue	Green blue	Yellow	White
Conductivity in PhNO$_2$ in r.o. (conc. ~ M/2,000) (20° C.)	57·0	Oxidizes	55·0	55·8	60·4	53·2
Magnetic moment at 20° C. (B.M.)	5·88	5·33	4·69	3·89	1·91	Diamag.

* The corresponding iodides of Mn^{II}, Fe^{II}, Co^{II} and Ni^{II}, for example, [Ph$_3$MeAs]$_2$ [NiI$_4$], have been prepared and are isomorphous. The nickel complex is red and again has a high magnetic moment (3·49 B.M.). With the tetraethylammonium cation similar behaviour is observed, the magnetic moments of [Et$_4$N]$_2$[NiCl$_4$] and [Et$_4$N]$_2$[NiBr$_4$] being in the range 3·8–3·9 B.M.

Table 3. PREDICTED MAGNETIC MOMENTS FOR SPIN-FREE BIVALENT NICKEL COMPOUNDS

Environment of Ni^{II} atom	$\mu_{eff.}$ (calculated)
(1) Free Ni^{++} ion ($^3F_4$). No electrical field. $S = 1, L = 3$ (assuming $h\nu = 0$)	4·47 B.M.
(2) As in (1) but using accepted value of $\nu = 2{,}347$ cm.$^{-1}$	5·56 B.M.
(3) As in (1) but assuming $h\nu = \infty$	5·59 B.M.
(4) Ni^{2+} ion in octahedral ligand field assuming no spin-orbital coupling	2·83 B.M.
(5) Octahedral Ni^{II}, for example, [Ni(H$_2$O)$_6$]$^{2+}$ or [Ni(NH$_3$)$_6$]$^{2+}$, using accepted value of spin-orbit coupling constant λ (varies from 200 to 324)	~ 3·1 – 3·2 B.M.
(6) Ni^{2+} ion in tetrahedral ligand field, assuming no spin–orbital coupling (taking $L = 1$)	3·16 B.M.
(7) As in (6), using the same value of λ as in the octahedral case but assuming that Δ is very large, that is, that the only configuration to be considered is $d_\gamma{}^4 d_\varepsilon{}^4$	3·6 B.M.*

* We are indebted for this figure to Dr. B. N. Figgis, who also reports that if Δ is not large enough to preclude configuration interaction, then the moment may be as large as 4·2 B.M. (unpublished work).

in order to obtain a large orbital contribution to the magnetic moment, one must have the possibility of re-arrangement of electrons in d_ε-orbitals when a magnetic field is applied. Three degenerate d_ε-orbitals containing a total of four electrons, as occurs for the Ni^{II} atom in a regular tetrahedral complex, provides an ideal example of this. A probable example of tetrahedral Fe^{II} occurs in the compound[15] FeI$_2$.2Ph$_3$P.

We have recently been studying complexes of the type M(hal)$_2$.2 pyridine of those bivalent metals which should give rise to both regular tetrahedral and octahedral arrangements; for example, Mn^{II}(d^5), Co^{II}(d^7) and Zn^{II}(d^{10}). In this connexion we have prepared compounds of the type [Ph$_3$CH$_3$As]$_2$+ M (hal)$_4$$^{2-}$, where hal = Cl, Br and I. These are obtained readily by adding the arsonium halide to the metal halide in alcoholic solution. In addition to the tetrahalide complexes of the metals listed above, we have obtained those of Fe^{II}, Ni^{II} and Cu^{II}. These are listed in Table 2. The Mn^{II}, Co^{II} and Zn^{II} complexes have the properties expected for four-covalent tetrahedral anions. The compounds are electrolytes in nitrobenzene, with the conductance expected for bi-univalent electrolytes. Only in the case of the Co^{II} compound is the orbital contribution to the magnetic moment helpful in deciding stereochemistry. The tetrahedral structure of the [CoCl$_4$]$^{2-}$ ion has been established in the compounds Cs$_3$CoCl$_5$ (ref. 16) and Cs$_2$CoCl$_4$ (ref. 17), the magnetic moments of which are close to that observed for [Ph$_3$MeAs]$_2$ CoCl$_4$. However, the magnetic moment of the Ni^{II} compound, 3·89 B.M.*, is unusually high; this points strongly to a tetrahedral arrangement of the ligands about the Ni^{II}. Moreover, for the orbital contribution to be so large, distortion from a regular tetrahedral arrangement is small. The expected magnetic moment for a tetrahedral Ni^{II} complex can only be calculated roughly owing to uncertainty as to the splitting, Δ, and the spin-orbit coupling constant. In Table 3 we list the calculated moments for Ni^{II} in various circumstances. The octahedral case has been carefully examined by Griffiths and Owen[18], who also emphasize that charge transfer between metal and ligand in metal hydrates occurs owing to weak σ-bonding.

The conclusion that these complex ions are tetrahedral is supported by X-ray diffraction investigations of single crystals of the compounds. With the exception of the Cu^{II} compound, which is expected to contain a tetragonal or square complex ion, the compounds of Mn^{II}, Fe^{II}, Co^{II}, Ni^{II}, and Zn^{II} are isomorphous, forming cubic crystals with cell edge 15·5 A. (Ni), space group $P2_13$, with four molecules in the unit cell. Though there are slight differences in cell constants, the intensities of corresponding diffraction maxima of the several compounds appear substantially the same, strongly indicating a regular tetrahedral arrangement for the Ni^{II} and Fe^{II} complexes, having accepted such arrangement for the Mn^{II}, Co^{II} and Zn^{II} complexes. Furthermore, the crystal symmetry is such that the metal atom lies on a three-fold axis, and taken in conjunction with the results of our other physical-chemical experiments, we conclude that it is surrounded by three equivalent chloride ions and one non-equivalent chloride ion also on the three-fold axis. The magnetic behaviour of [Ph$_4$As]$_2$ [NiCl$_4$] in a suitable non-co-ordinating solvent should prove of interest, because under these conditions the constraining effects, if any, of the lattice of neighbouring ions will be removed.

These investigations are being extended to include other bivalent and tervalent metals, and to complete the crystal structure determination of [Ph$_3$MeAs]$_2$ [NiCl$_4$]. The important feature which emerges from these studies is that when considering cases where crystal field forces are opposed by others, particularly those arising from bonds, the crystal field forces may be swamped and the structure be that determined by bond and lattice interactions.

1957	1156 pages	£21

The YEARBOOKS consist of full abstracts, which originally appeared monthly in loose-leaf form. At the end of each year these leaves are collected into convenient bound volumes. Every original contribution in the field, in a large number of international journals, is represented by a full abstract—that is to say, not by a brief summary, but by an account so full that, in almost all cases, the original journal paper need not be consulted. The successive Yearbooks therefore constitute a coverage of the entire field.

◆

RESEARCH MANAGEMENT

Approximately 250 pages per year. Annual subscription £3

This is a new quarterly journal, published jointly by Interscience Publishers and Industrial Research Institute, which deals with questions of a general nature common to all kinds of industrial research. It will publish reports on case histories of development, problems of personnel, organization of laboratories, social effects of industrial research, etc. The journal is intended for research managers and all who have a general interest in research. *Part 1 of Volume I has just been published.*

Physiology, Anatomy and Health

Part I: Physiology and Anatomy

L. J. F. BRIMBLE, B.SC., F.R.S.E., F.R.S.A., F.L.S.
T. H. HAWKINS, M.SC., M.ED.
KATHLEEN HAWKINS, M.B., CH.B.

An elementary book, well illustrated with line drawings, half-tone photographs and about a dozen radiographs. It should satisfy the needs of nurses in training and candidates for the G.C.E. ('O' level) in Human Biology and Hygiene. It should also appeal to Social Workers, those interested in First Aid, Physical Fitness, etc. 'One rarely sees a volume so tightly packed with essential knowledge and information being also such a handy size . . . excellent.'—*Health Education Journal.*
The second part, Health, will be published later. Part 1: 7*s*

A School Course of Biology

L. J. F. BRIMBLE, B.SC., F.R.S.E., F.R.S.A., F.L.S.

The fourth edition of this well-known, comprehensive text-book has been entirely re-written and enlarged in collaboration with L. M. J. Kramer, and new drawings and photographs added. It should meet the requirements of all candidates for the G.C.E. ('O' level), but in many places attention has been diverted from an actual syllabus, in order to include aspects of an economic and everyday nature in biology which will attract the interest of the student. 18*s*

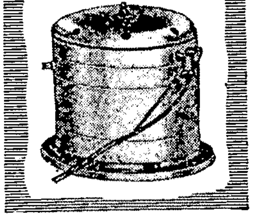
Vibrators *for fatigue testing*

Guided missiles, aircraft and all forms of industrial components . . .



★ *Our Technical Dept. is always available to give assistance on any Vibration problems.*

TYPE V1001. This vibrator is of the moving coil type with a wound field magnet energised from an external source of direct current. It is continuously rated and therefore suitable for extended fatigue testing as well as for intermittent use in research, development and production work.

The useful frequency range is up to 5 kc/s.

The design of the vibrator is such that the electrical impedance of the "speech coil" shows only a slight rise at the higher frequencies and this obviates the need for frequent output transformer tap changing as the frequency is varied.

SPECIFICATION

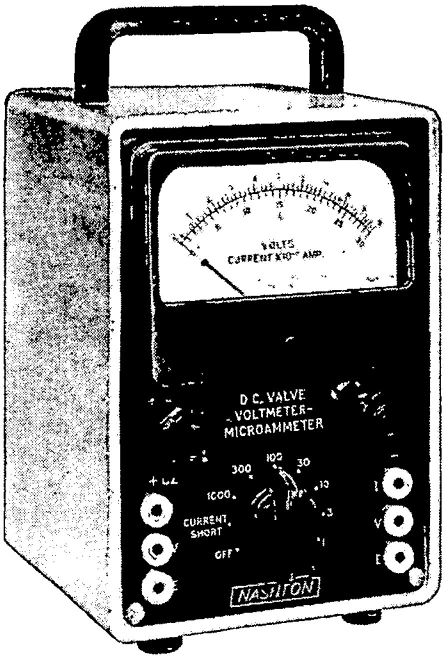
ANOTHER NEW **NASHTON** INSTRUMENT



DC Valve Voltmeter – Micro Ammeter

Seven DC voltage ranges up to 1000 v. full scale
Seven DC current ranges down to 0.1 micro amps full scale

★ Accuracy better than 3% on eleven ranges ★ High input impedance ★ "Balanced to earth" measurements possible ★ High stability against mains fluctuation ★ Top quality moving coil meter to B.S. 89 : 54 ★ Fully guaranteed for one year from date of purchase.

This new addition to the NASHTON range of miniaturised electronic test gear is eminently suitable for Reverse Current measurement of Germanium and Silicon diodes: Leakage current measurement of capacitors: Splash current measurement of thermionic diodes and high resistance measurement up to 10,000 Megohms using an external voltage supply.

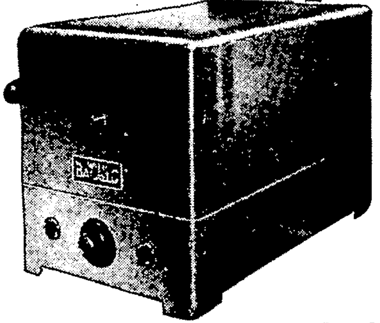
WILD-BARFIELD LABORATORY MUFFLES

ENSURE PERFECT PERFORMANCE

This horizontal rectangular muffle is ideal for such purposes as incineration, burning off precipitates, and the heat-treatment of small samples of metal. The proportions have been fixed after careful examination of such laboratory needs. Temperature control by a hand-operated energy regulator type controller. Maximum recommended temperature — 1,000°C (1832°F). Wild-Barfield's great experience ensures perfect performance and a long trouble-free life. Full details on request.



Now available from stock

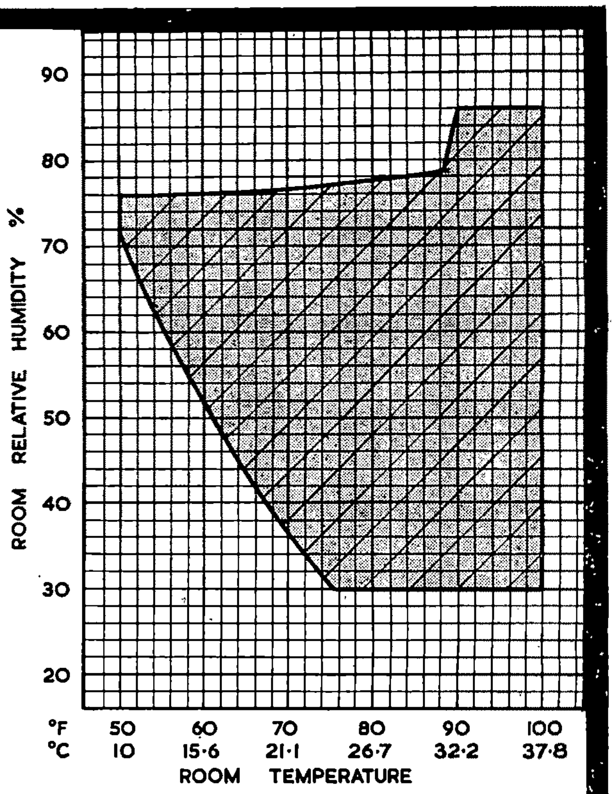
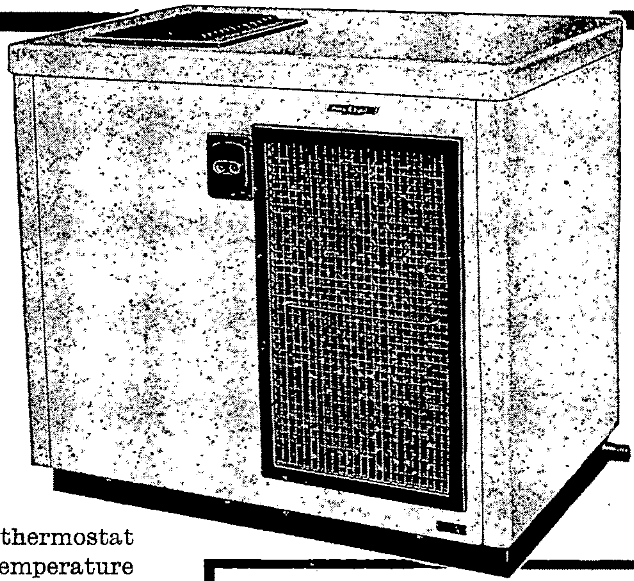
PRECISION HUMIDITY AND TEMPERATURE CONTROL

to any conditions within this area





Rooms up to approximately 3,000 cu. ft. can be accurately conditioned with this air-conditioning cabinet, and conditions have been maintained within ±0.5F. and 0.75% relative humidity. The cabinet is provided with an air outlet raised above bench level. Larger units are available for special applications. The specification includes a replaceable glass silk filter for air entering the cabinet; centrifugal fan complete with belt drive fan motor and starter; cooling coil of up to 35,000 B.T.U.'s extraction per hour for reduction of either temperature or humidity; air heater with built-in high limit thermostat; room thermostat with relay to operate electric heater when temperature low, or cooling coil when temperature too high; humidistat to control humidity; evaporative humidifier.

PYE
PYE FOR GAS LIQUID CHROMATOGRAPHY

This new type of equipment gives high resolution and sensitivity plus. It uses the katharometer technique—the overall sensitivity of the system being improved by as much as forty times by means of the low noise d.c. amplifier connected between the katharometer bridge and the recorder. Sensitivity can be changed by factors of 2, 5, 10 during a run over a wide range—100 millivolts to 12.5 microvolts f.s.d. on the potentiometric recorder.

Good temperature and pressure control ensures stability at such high sensitivity.

Components are also available: please write for a leaflet giving full details.

Clinical biochemical methods

by A. L. TARNOKY

This is essentially a bench book, based on routine practice at the Royal Berkshire Hospital, Reading, where the author is biochemist. It selects, for the tests in most regular demand in clinical laboratories, methods that give results in a reasonable time, are accurate enough for clinical purposes, and do not require highly specialized apparatus. Instructions are detailed, simple, and straightforward, and are set out in clear steps for easy reference at the work bench; they reflect the author's experience in industry and hospitals. Just published. **Price 50s. net**

SHEEP HÆMOGLOBINS

By Dr. T. H. J. HUISMAN, G. van VLIET and T. SEBENS
Department of Paediatrics, State University of Groningen

Some Genetic and Physiological Aspects of Two Different Adult Hæmoglobins in Sheep

INVESTIGATING more than 4,500 sheep of different breeds, Harris and Warren *et al.*[1–3] described the presence of two electrophoretically different types of adult hæmoglobin. The hæmoglobin moving more rapidly towards the anode at *p*H 8·6 was called Hb-*A* and the slower migrating component Hb-*B*. The occurrence of the two sheep hæmoglobins appears to be genetically determined by two genes, each responsible for the formation of one type of hæmoglobin. Large differences in the relative frequencies of the two types of sheep hæmoglobin were found from breed to breed; the lowland breeds have predominantly the Hb-*B* type and the highland breeds the Hb-*A* type. Two types of adult hæmoglobin were also found in Dutch sheep (Texel breed)[4]. They are designated Hb-I (slow-moving in paper electrophoresis) and Hb-II (fast-moving hæmoglobin). It is not known whether these two types of hæmoglobin are identical with the hæmoglobins *B* and *A*, respectively, but the electrophoretic patterns are closely similar, and moreover, the Dutch breed is closely related to some English breeds, such as Leicester and Lincoln. Studying the physical and chemical properties of the two hæmoglobins[4], differences were found in their resistance to denaturation by alkali, in electrophoretic and chromatographic behaviour, in solubility in concentrated salt solutions and in amino-acid composition.

The incidence of the two types of hæmoglobin in 300 sheep of the Texel breed has been determined. 71 per cent of these animals had hæmoglobin of type Hb-I, 3 per cent Hb-II and 26 per cent both types. These values are of little importance, as the genetic pattern of one breeding ram strongly influences the gene frequencies in a herd.

Blood samples from 80 animals belonging to one pedigree were also examined. The results are given in Fig. 1. The first ram, used in 1954 and in 1955, was homozygous for Hb-I; three of the five ewes (year 1954) and four of the five ewes of 1955 were heterozygous for both hæmoglobins I and II. The gene responsible for the production of Hb-II was transmitted to about half their descendants. One of the male lambs, born in 1954 and heterozygous for Hb-I and II, was used as breeding-ram in 1956 and 1957. Many ewes being impregnated by this ram were heterozygous for the two hæmoglobins. So it was possible to get figures on the inheritance of both types of hæmoglobin. The results shown in Table 1 indicate that the two types of hæmoglobin are inherited in a simple Mendelian manner, resembling the genetic pattern of some types of human hæmoglobin.

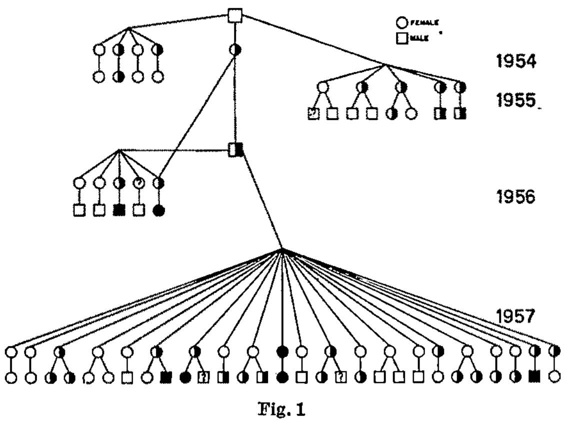

Fig. 1

Table 1. GENETIC PATTERN OF THE TWO SHEEP HÆMOGLOBINS I AND II
The values in parentheses indicate the expected numbers of lambs belonging to one of the three combinations

Male	Female		Lambs			
		No.	Total	I and I	I and II	II and II
I + I	I + II	13	18	7 (9)	11 (9)	
I + II	I + I	27	35	18 (17–18)	17 (17–18)	
I + II	I + II	10	12	3 (3)	4 (6)	5 (3)

During these investigations, it was observed that samples of venous blood (obtained by puncture of the vena saphena) of sheep homozygous for Hb-II seemed to be oxygenated to a greater extent than were the corresponding blood samples of sheep homozygous for Hb-I. Analyses of the oxygen saturation[5] of a few samples of venous blood showed values of 85, 87 and 90 per cent for the sheep homozygous for Hb-II, and 69, 72 and 75 per cent for the sheep homozygous for Hb-I. These preliminary results prompted us to study the oxygen affinities of the blood from the two types of sheep as well as of the hæmoglobins in solution. Small samples of blood (1·0 ml.) in a tonometer of 150 ml. capacity[6] were exposed to various gas mixtures containing known percentages of oxygen and a fixed percentage (40 mm. mercury) of carbon dioxide. Equilibration was obtained by rotation of the tonometer in a water-bath at 37° C. for 20 min. The percentage saturation with oxygen was measured spectrophotometrically[5], and the *p*H values of the samples were also determined. Hæmoglobin solutions were prepared by laking fresh, washed erythrocytes with an equal volume of distilled water and 0·4 vol. of toluene for 3 hr. at 2° C., followed by centrifugation at high speed in the cold for 30 min. Following the technique described by Allen *et al.*[7], both hæmoglobin solutions were dialysed for 16 hr. simultaneously against the same sample of 0·4 *M* phosphate buffer of *p*H 7·5, containing 1·0 *M* glucose. The oxygen affinities of these hæmoglobin solutions, containing hæmoglobin in a concentration varying between 14 and 17 gm. per 100 ml., were measured using the same method as described for the blood samples. Possible modifications of the oxygen saturation of the samples pro-

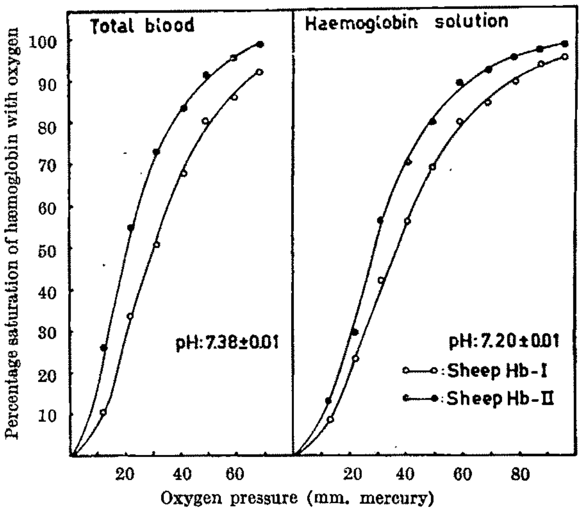

Fig. 2. Oxygen dissociation curves of the two sheep hæmoglobins

duced by differences in the carbon dioxide tension of the blood and hæmoglobin sample or by deviations in the pH could be excluded, since a constant carbon dioxide tension (40 mm. mercury) was applied and the pH values of the samples after equilibration varied only within narrow limits (± 0·01).

Fig. 2 illustrates the results. It was found that the oxygen dissociation curve of the blood obtained from a sheep homozygous for Hb-II was shifted to the left, indicating a higher oxygen affinity of blood of type Hb-II. This finding may be explained by intrinsic differences of the hæmoglobin molecule rather than by differences in the environment of the hæmoglobin, since the oxygen affinities of the dialysed solution of blood of type Hb-II were consistently higher than those of the corresponding dialysed solution of blood of type Hb-I. These results suggest that hæmoglobin of type Hb-II has adaptive significance and may have originated by mutation in sheep living at high altitude. It is worth noticing that the frequency of hæmoglobin of type Hb-*A* described by Evans *et al.*[3], which is probably identical with our Hb-II, is relatively high in the mountain and hill breeds, suggesting predominance of these animals by natural and human selection. This is remarkable, as any advantage in possessing this type of hæmoglobin with increased oxygen affinity can scarcely be assumed at this moderate altitude.

The increased oxygen affinity allows the blood of a sheep of hæmoglobin type Hb-II living at sea-level to take up more oxygen in the lungs, but also hampers the liberation of the oxygen from the blood in the tissues. So the oxygen, which is present in the blood, is less available to the tissues, resulting in an anoxia. Consequently, an increase of the total hæmoglobin content of the blood may occur. Table 2 illustrates a significantly higher total hæmoglobin content of the blood of the sheep of type Hb-II compared with the values found in sheep of type Hb-I. The values found in sheep heterozygous for both hæmoglobins are intermediate.

Table 2. TOTAL HÆMOGLOBIN LEVELS OF THE BLOOD OF LAMBS TWO MONTHS OLD POSSESSING THE TWO DIFFERENT HÆMOGLOBINS

Type	No.	Hæmoglobin (gm. per 100 ml.)	*P*-value
Hb-I	70	11·7 ± 0·1	I to I/II < 0·01
Hb-I + Hb-II	25	12·2 ± 0·15	I to II < 0·001
Hb-II	4	13·2 ± 0·15	I/II to II < 0·01

The different oxygen affinities may also offer an explanation for deviations in the relative amounts of the two hæmoglobins in sheep heterozygous for the Hb-I and Hb-II, when these animals are suffering from a severe anæmia, caused, for example, by chronic strongylosis and distomatosis. It was found (Table 3) that a decrease of the total hæmoglobin content from 11 gm. per 100 ml. to 8 gm. per 100 ml. is compensated by an increased production of hæmoglobin of type Hb-II, increasing the capacity of the blood for oxygen. When, however, the total hæmoglobin content is decreased to very low values (2–4 gm. per 100 ml.), increased production of Hb-I occurs, which facilitates the liberation of oxygen from the blood to the tissues.

Table 3. RELATION BETWEEN THE TOTAL AMOUNT OF HÆMOGLOBIN AND THE PERCENTAGES OF THE TWO ADULT HÆMOGLOBINS IN SHEEP HETEROZYGOUS FOR BOTH TYPES

Sheep	Total hæmoglobin (gm. per cent)	Hb-I (per cent)	Hb-II (per cent)
A	11·2	56	44
B	8·4	36	64
C	4·2	70	30
D	1·8	76	24

It is evident from this work that the presence of two different types of hæmoglobin in the adult sheep is a genetically controlled abnormality of hæmoglobin synthesis. The increased oxygen affinity found for hæmoglobin of type Hb-I may offer an explanation for its origination in sheep living at high altitude.

These investigations were supported by a grant of the Dutch Organization for Pure Research (Z.W.O).

Hæmoglobin Types in Different Species of Sheep

IN previous reports[1,2] we described some characteristic properties of two different hæmoglobins (called Hb-I and Hb-II) in Dutch sheep (Texel breed), which are probably identical with the sheep hæmoglobins *B* and *A* discovered by Harris, Warren *et al.*[3-5]. Hb-II is distinguished from Hb-I by its electrophoretic and chromatographic behaviour, by a higher resistance to denaturation by alkali, a decreased solubility in concentrated phosphate solutions, and a different amino-acid composition[1]. Moreover, erythrocytes, as well as dialysed hæmoglobin solutions of sheep homozygous for Hb-II, show an increased affinity for oxygen[2]. These results suggest that Hb-II is of adaptive significance and that this hæmoglobin-type originated in domesticated breeds from sheep living at high altitude.

To confirm this hypothesis we studied blood samples from some different species of sheep living

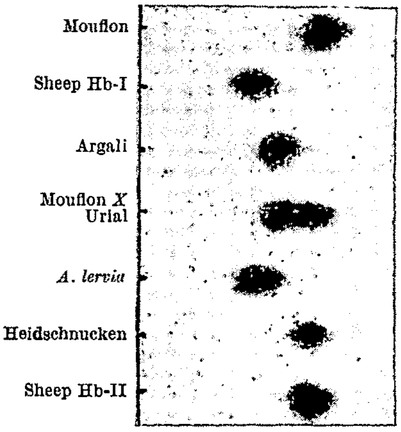

Fig. 1. Paper-electrophoretic separation of the hæmoglobins of different species of sheep

in the Zoological Gardens, Artis (Amsterdam) and Blijdorp (Rotterdam). We examined the following species of the genus *Ovis*: the Argali (*Ovis ammon*), living in the mountains of North and Central Asia above the timber-line; the European Mouflon (*Ovis musimon*), originally living in South and Central Europe and at present in the mountains and forests of Corsica and Sardinia; a cross-bred between the Mouflon and the Urial (*Ovis vignei*) and the Heidschnucken, a native breed of the Lüneburger Heide (Germany) which is most probably descended from the European Mouflon. One species of the genus *Ammotragus* (*A. lervia*), which lives in the mountains of North Africa, was also investigated. The hæmoglobins from one Argali, five Mouflons, one cross between the Mouflon and the Urial, four Heidschnucken and two *A. lervia* were examined by denaturation with alkali, by paper electrophoresis (0·06 *M* veronal buffer solution of *p*H 8·8) and by salting-out experiments. The oxygen dissociation curves of the total blood samples as well as of the hæmoglobin solutions were also established. The techniques used are described in previous papers[1,2].

The hæmoglobins of the different sheep showed the same high resistance to denaturation by alkali found for Hb-II, indicating that none of them is identical with Hb-I. The results of the paper-electrophoretic examination of the hæmoglobins are shown in Fig. 1. The hæmoglobins of the Mouflon and of the Heidschnucken show the same fast electrophoretic mobility found for Hb-II; the hæmoglobin of the cross between the Mouflon and the Urial consists of two components, the fast moving one being identical with that of the Mouflon. The hæmoglobin of the Argali moves slightly faster than Hb-I and shows almost the same mobility as the second component of the cross, probably the hæmoglobin of the Urial. Finally, the hæmoglobin of *A. lervia* can scarcely be differentiated from Hb-I.

The solubilities of Hb-I, and the hæmoglobins of the Mouflon, Argali and *A. lervia* in phosphate buffers of different concentrations are given in Table 1. The hæmoglobin of the Mouflon and Hb-II show the same low solubility; these hæmoglobins are completely insoluble in 2·8 *M* phosphate buffer. The solubilities of the hæmoglobins of the Argali and of *A. lervia* are intermediate between those of Hb-I and Hb-II, but they are not identical.

Table 1. SOLUBILITY AS PERCENTAGE IN SOLUTION OF SHEEP HÆMOGLOBINS IN PHOSPHATE BUFFERS (*p*H 6·5) OF DIFFERENT MOLARITIES

Species	2·10 *M*	2·59 *M*	2·80 *M*	2·94 *M*
Dutch Sheep Hb-I	100	100	90·5	24·0
Dutch sheep Hb-II	100	39·3	0·2	0
Mouflon	100	48·5	3·5	0·1
Argali	100	92·1	10·9	0·1
A. lervia	100	96·2	24·6	20·3

The oxygen dissociation curves of the total blood samples and of the dialysed hæmoglobin solutions are shown in Fig. 2. The oxygen affinities of the blood of the Mouflon and of the Heidschnucken are identical with that of sheep homozygous for Hb-II. The oxygen affinity of the blood of the Argali is still greater, while the oxygen dissociation curve of the blood of *A. lervia* is intermediate between those of the blood derived from sheep homozygous for Hb-II and Hb-I. Similar results were obtained for dialysed hæmoglobin solutions, indicating that the differences in oxygen affinity are inherent in intrinsic differences of the hæmoglobin molecules rather than due to differences in their environment.

From these results it may be concluded that Hb-II in the breed 'Texel' originated in the (European) Mouflon, confirming the generally accepted opinion that Dutch sheep (and perhaps also English sheep) are partially descended from this animal[6]. The Heideschnucke also possesses Hb-II. In none of the species investigated was Hb-I present. This hæmoglobin in Dutch sheep may therefore have originated in other types, for example Lincoln and Leicester sheep, which possess Hb-I only (unpublished results). The descent of these sheep is unknown. The presence of Hb-I in these breeds may have been derived from an unknown species living at sea-level.

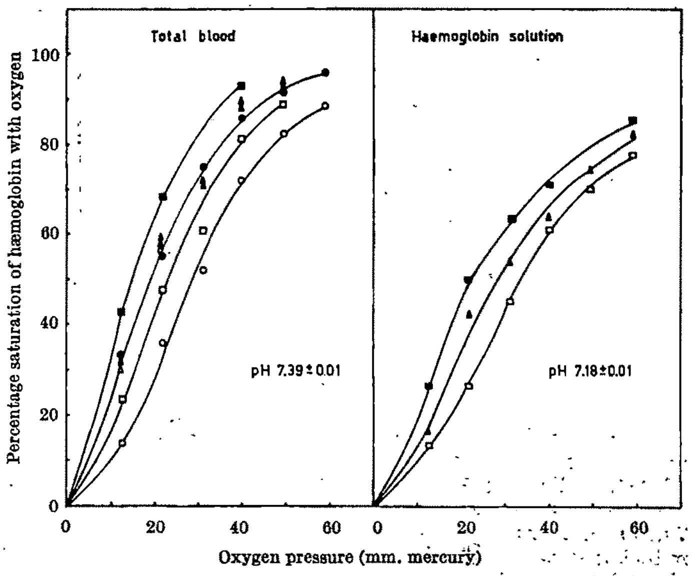

Fig. 2. Oxygen dissociation curves of blood samples of sheep: ○—○, Dutch sheep, breed 'Texel', homozygous for Hb-I; ●—●, Dutch sheep, breed 'Texel', homozygous for Hb-II; □—□ *A. lervia*; ■—■, Argali; △—△, Heidschnucken; ▲—▲, Mouflon

It is remarkable that sheep living at high altitude (Argali) possess a hæmoglobin type with an oxygen affinity still greater than that of the Mouflon, while *A. lervia*, living at about 1,000 m. above sea-level, possess a hæmoglobin the oxygen dissociation curve of which is between those of Hb-II and Hb-I. It seems, therefore, that a specific type of hæmoglobin is present in these animals with its own chemical and physiological properties. Thus four different types of hæmoglobin can be demonstrated in sheep; in the genus *Ovis* besides Hb-I and Hb-II (identical with the hæmoglobin of the Mouflon) there is the hæmoglobin of the Argali, and in the genus *Ammotragus* the hæmoglobin of *A. lervia*.

These investigations were supported by a grant of the Dutch Organisation for Pure Research (Z.W.O.). We are much indebted to Drs. Jacobi (Artis, Amsterdam) and van Bemmel (Blijdorp, Rotterdam) for their aid in collecting the blood samples from the different animals.

VASCULAR PERMEABILITY FACTORS IN THE SECRETION OF THE GUINEA PIG COAGULATING GLAND

By JULES FREUND

National Institute of Allergy and Infectious Diseases, Bethesda, Maryland

AND

PROF. A. A. MILES, C.B.E., P. J. MILL and D. L. WILHELM

Lister Institute of Preventive Medicine, London

THE secretion of the coagulating gland of the male guinea pig induces a hypotensive shock on intravenous injection into the guinea pig and the rabbit, and œdema on local injection into the tissues[1].

The induction of œdema suggested that these effects were produced by substances increasing the permeability of the blood vessels. By preparative starch electrophoresis[2] in phosphate buffer at *p*H 8·0, we have isolated two main protein components (fractions I and II) from the fluid. Fraction I is hypotensive and a highly potent permeability factor in the guinea pig and rabbit; fraction II coagulates the contents of the seminal vesicles and is a moderately potent permeability factor in the rat and the rabbit, owing its activity in the rat to the liberation of histamine. Neither is a 'spreading-factor' in connective tissue.

The fluid was harvested from large numbers of animals and freeze-dried. On reconstitution to the original volume in water, a small portion of the material was insoluble and discarded. The soluble portion contained 150 mgm./ml. protein, in which five components (fractions 0, I, II, III, IV in descending order of mobility) were separated by paper electrophoretic analysis[3]. Fractions 0, III and IV represented 1, 10 and 4 per cent of the total protein, and had no substantial toxic or coagulating activity. Fractions I and II represented 16 and 69 per cent of the total proteins, respectively; although by starch electrophoresis the percentage yields of the two protein fractions were nearly equal.

Fraction I had an electrophoretic mobility rather greater than that of guinea pig serum albumin. It was homogeneous in the ultracentrifuge with an S_{20w} of 4·4, indicating—on the assumption of an isodiametric molecule—a molecular weight of about 70,000. On hydrolysis it yielded some 11 per cent of reducing sugars. It had feeble caseinolytic activity[4], about 1/5000 that of crystalline trypsin, disappearing on storage even at − 10° C., and contained a strong *p*-toluenesulphonylarginine methyl esterase[5], which had the same stability to heat as the permeability factor (losing only 20 per cent of its activity after 5 min. at 95° C.) and it was not antagonized by soya-bean trypsin inhibitor.

The permeability-increasing potency, measured in terms of blue exudation into the skin of animals with pontamine blue in their circulation, is expressed in Table 1 as the number of 'effective blueing doses'[6,7] per mgm. Fraction I is highly active in the guinea pig, and even more so in the rabbit; in both animals it was not inhibited by soya-bean trypsin inhibitor, and only slightly inhibited by mepyramine maleate and by the guinea pig serum fraction containing inhibitor of the serum permeability factor[9]; in the rat peritoneal cavity[10] it did not liberate histamine.

Table 1

Preparation	Effective blueing doses per mgm. in: Guinea pig	Rat	Rabbit
Original fluid (guinea pig)	20,000	1,100	200,000
Fraction I	50,000	50	600,000
Fraction II	500	1,300	4,000
Histamine (ref. 8)	32,000	1,400	37,000

Injected intravenously, it reproduced the effects described by Freund and Thompson[1] for the whole gland fluid; doses of 2–4 mgm./kgm. body-weight induced moderate shock in the guinea pig and rabbit, which in the guinea pig was slightly lessened by systemic mepyramine; whereas 16 mgm./kgm. had little effect in the rat.

Fraction II had three times the coagulating potency of the original fluid, but no caseinolytic or arginine esterase activity. The main observations of Gotterer and others[11] on the nature of the coagulating principle were confirmed. Intravenous doses of 2–4 mgm./kgm. were non-toxic to guinea pigs, and 4–7 mgm./kgm. were only slightly toxic to rabbits; but in rats 10–16 mgm./kgm. induced an effect like that of egg-white[12], including œdema of the snout.

In the rat, fraction II appears to owe its activity to the release of histamine, since its permeability effect was inhibited by mepyramine; and it liberated histamine in the rat peritoneal cavity[10], in this respect being about equipotent with the synthetic histamine liberator, compound 48/80 (ref. 13).

The increase in permeability induced by fraction II in the rat, like that of fraction I in the guinea pig and rabbit, was not affected by dialysis in 'Cellophane' sacs.

It is of interest that starch-block electrophoresis of the fluid from the *rat* coagulating gland yielded only two protein fractions, which had about the same respective mobilities as fractions I and II of the guinea pig fluid. Neither fraction was toxic to, nor had a significant permeability effect in, the three test animals. As in guinea pig gland fluid, the coagulating activity was present in the less mobile fraction II. The analogous status of rat and guinea pig fractions II is strengthened by the fact that each was capable of coagulating the seminal vesicular material from the other species.

Our results are consistent with the view that the main toxin, for guinea pig and rabbit, of fluid from the coagulating gland of the guinea pig is the permeability factor in fraction I, which appears to be a glycoprotein with arginine esterase activity. This toxin is in many important features unlike the globulin permeability factors in human[14] and other mammalian sera[7,9]. The permeability-increasing potency is negligible in the rat. On a weight basis, it is nearly twice that of histamine in the guinea pig; and in the rabbit it is outstanding among the potencies of all natural and synthetic permeability factors we have tested, being sixteen times that of histamine. On a molar basis, the protein of fraction I is, in these two animals, respectively 1,000 and 9,000 times as potent as histamine, suggesting an enzymic mode of action.

That fraction I is toxic for the homologous animal, particularly for the small blood-vessels, may be irrelevant to its function in the external glandular secretion of which it is a constituent; but its pharmacology may provide a clue to the mode of action of the enzyme-like, protein permeability factors present in blood and tissue fluids[15].

SODIUM FLUOROACETATE AS A PROTECTING AGENT AGAINST IRRADIATION

By Prof. Z. M. BACQ and Dr. P. FISCHER

THE mortality as well as the somatic damage caused to living organisms by X- or γ-rays are greatly reduced by the previous administration of various compounds. To be effective, these substances must be injected into the animal immediately before irradiation. Cysteine, cysteamine and its derivatives were found to be most potent in this respect; many other compounds were also found to be effective (see refs. 1 and 2 for a review of the literature).

It now appears that deoxyribonuclease plays an important part in the destruction of deoxyribonucleic acid that follows irradiation. Deoxyribonucleic acid is localized in the cell nucleus, whereas acid deoxyribonuclease was found by de Duve *et al.*[3] to be concentrated in the small mitochondria, also called lysosomes. 'Neutral' deoxyribonuclease requires magnesium ions for its activity[4]. Therefore, it was thought that agents complexing magnesium ions would affect the activity of the enzyme and might protect against irradiation. Attempts to do so by intraperitoneal injections of large doses of sodium citrate (up to 1·25 gm./kgm.) to the mouse failed: very irregular results were obtained[5], presumably because injected citrate penetrates many tissue barriers with great difficulty (see ref. 6). Other chelating agents such as diethyldithiocarbamate and ethylenediamine tetraacetate, however, were found to protect mice against irradiation[7].

The administration of sodium fluoroacetate was known from the work of Peters and collaborators[8] (see also ref. 9) to accumulate citrate in animal tissues. The following experiments were performed to see whether the intracellular accumulation of citrate produced by the injection of fluoroacetate would protect the mouse against irradiation.

Lots of 10 mice of the *C57* black pure strain and weighing 18–22 gm. were given 750–775 r. at the average rate of 90 r./min., using a Siemens 200-kV. 'Stabilivolt'. Sodium fluoroacetate (Monsanto), when used, was injected intraperitoneally at a dose of 4–5 mgm./kgm. The toxicity of fluoroacetate for our mice was measured by the 'up-and-down' method of Dixon and Moore[10], as described by Kimball *et al.*[11]: LD_{50} was found to be $8 \cdot 3 \pm 1 \cdot 4$ (standard error) mgm./kgm. In our experiments, 4–5 mgm. sodium fluoroacetate/kgm. killed about 30 per cent of the control mice within 48 hr. To distinguish between that early death and death by irradiation which occurs later, the number of surviving animals was expressed as a percentage of those which survived after the first two days.

If injected 5 hr. or even 2 hr. before irradiation, sodium fluoroacetate reduced the mortality produced by X-irradiations (see Fig. 1). After 7 days, 42 per cent of the irradiated mice had died, whereas mice pre-injected with sodium fluoroacetate were all alive; after 14 days, the mortality figures for the two groups were 90 and 20 per cent; after 21 days, 94 and 40 per cent. It will be seen in Fig. 1 that sodium fluoroacetate given just before or just after irradiations is without effect on the mortality, which reaches 47·5, 90·5 and 95 per cent after 1, 2 or 3 weeks. In other series, sodium fluoroacetate was injected 24 hr. before, or 5 hr. after, irradiation; no protection was observed in either case.

It is now believed that fluoroacetate is not toxic by itself but only after it has been transformed into fluorocitrate, a competitive inhibitor of aconitase, an enzyme of the tricarboxylic acid cycle (for a review, see ref. 12). Accumulation of citrate in the tissues of the rat follows after a latent period[13] of 30–60 min.; the highest level of citrate in the tissues of the rat was observed 2–8 hr. after the injection of non-lethal doses of the poison[13,14].

The curves of Fig. 2 show that the tissues of the mouse behave like the tissues of the rat: sodium fluoroacetate produces an accumulation of citrate (curve *A*) with a maximum 2–14 hr. after the injection of the poison. Irradiation 5 hr. after injection of sodium fluoroacetate (curve *B*) reduces the level of accumulated citrate, which returns to normal level within 24 hr., whereas 48 hr. are required in the case of non-irradiated mice. Irradiation alone (curve *C*) produces no measurable change in the citric acid content of the tissues. When the mice are irradiated immediately after injection of sodium fluoroacetate (curve *D*), accumulation of citrate seems to be somewhat delayed, at least in the kidneys; high levels are reached as in sodium fluoroacetate controls, followed by a more rapid return to normal.

Fairly similar results were observed in spleen and brain. In heart, however, the antagonizing effect of X-rays on the accumulation of citrate induced by sodium fluoroacetate was less noticeable; the disappearance of citric acid under the influence of X-rays was delayed in that radio-resistant organ.

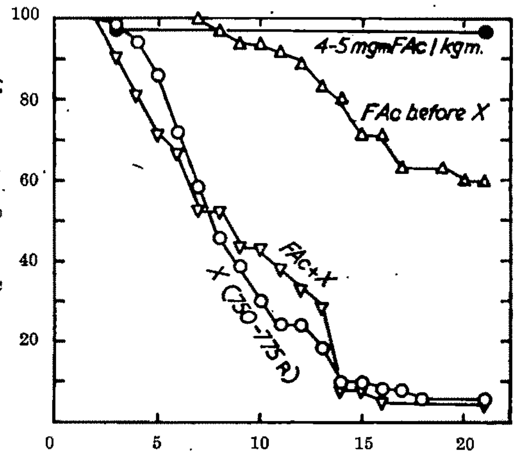

Fig. 1. Protection of the mouse against irradiation (*X*) by sodium fluoroacetate (*FAc*) injected 5 hr. before. The number of animals used in each experiment was: 4–5 mgm. *FAc*/kgm., 45; *X* (750–775 r.), 50; *FAc* before *X*, 40; *FAc* + *X* (simultaneously), 50

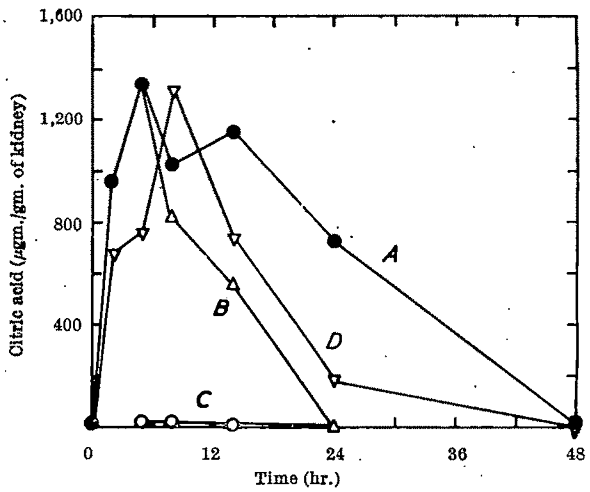

Fig. 2. Citric acid content of the mouse kidney. Curve *A*, sodium fluoroacetate only, 5 mgm./kgm.); curve *B*, 775 r. given 5 hr. after sodium fluoroacetate; curve *C*, 775 r. only; curve *D*, 775 r. given immediately after sodium fluoroacetate. Citric acid was estimated by the method of Taylor (ref. 16)

Our observations on the effects of sodium fluoroacetate and X-rays on the citric acid content of the tissues of the mouth are comparable to the results published by DuBois *et al.*[15], who demonstrated that rats, guinea pigs and mice receiving sodium fluoroacetate 3 hr. or more after irradiation accumulate less citrate than non-irradiated controls.

It may very well be that fluoroacetate somehow affects the sensitivity of the cells to X-rays by reducing their oxidative metabolism; many of the so-called radio-protectors are, in fact, toxic agents. Fluoroacetate may, however, protect the cells in a more specific way, accumulating citrate, complexing the intracellular magnesium ions, and so affecting the deoxyribonuclease activity, as we have supposed: such a mechanism, still very speculative indeed, is supported by the results of our experiments, although not proved, of course. If the availability of free magnesium ions must be reduced to afford radio-protection, it would seem from the evidence presented here that such a reduction must be completed at the very moment of the irradiation; sodium fluoroacetate injected only at that time piles up citrate too late, and no longer protects.

A Revision of the Azulene Structure

In a previous communication from this laboratory[1], a crystal structure for azulene based on the non-centrosymmetric space group *Pa* was reported. It was assumed that the (0*k*0) halving was accidental and it was easy to place the two molecules with respect to the glide plane in such a way that an almost exact halving of these spectra was obtained. This structure led to reasonably good agreements in all the principal zones, the discrepancies between observed and calculated structure factors being about 12 per cent for (*h*0*l*), 14 per cent for (*hk*0) and 20 per cent for (0*kl*). A convincing electron density map for the projection on (010) was obtained, and it was confidently expected that a further analysis of the full three-dimensional crystal data would lead to a complete refinement of the structure, with significant values for the bond-lengths and electron distribution. Our preliminary structure was further supported by an independent investigation made by Takeuchi and Pepinsky[2], who obtained almost identical results. Neither of us saw any evidence of disorder in our X-ray photographs, although Günthard[3] has shown from a comparison of the entropies of azulene and naphthalene that there may be some disorder in the azulene crystal.

We now find that our preliminary structure is wrong, or at least it constitutes only half the truth, and the structure must in fact be disordered, as postulated by Günthard. This is one of the most remarkable examples that we have encountered of a preliminary structure based on data from three crystallographic zones being wrong in spite of quite reasonably good agreements in the structure factor calculations.

When we proceeded to refine the structure from our full three-dimensional data it was not long before we encountered difficulty. Various difference syntheses and generalized projections did not lead to much refinement, and after these had been carried out the average discrepancies between calculated and observed structure factors over all the 670 observed (*hkl*) reflexions was 23·4 per cent. With the help of Prof. Ray Pepinsky and Dr. V. Vand we then attempted a least squares refinement of the three-dimensional data, but after three cycles of such refinement the average discrepancy only decreased to 22·4 per cent.

Something was clearly wrong, so we next examined the possibility that the space group might after all be $P2_1/a$, as indicated by the halvings, and the structure really centrosymmetric. The atomic co-ordinates deduced previously were referred to a new origin at the centre of the molecule which was taken to coincide with a centre of symmetry in $P2_1/a$, and the atoms were given half-weight. This procedure postulates the superposition of two molecules in the previous orientation except for the inversion of the second molecule through the symmetry centre. Physically, and according to the chemical evidence, this must correspond to a simple random reversal of direction of successive azulene molecules in the crystal. A view of the resulting superposition of two molecules is shown in Fig. 1.

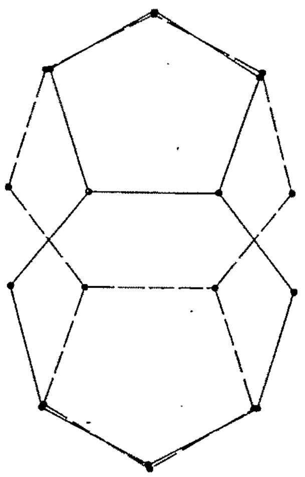

Fig. 1. Superposition of two azulene molecules

On this basis structure factors were calculated, and after some preliminary refinement they showed distinctly better agreement with the observed values than was the case with the non-centrosymmetric structure. Again with the help of Prof. Pepinsky and Dr. Vand eight cycles of least squares refinement were then applied on this new basis, and as a result the overall discrepancy dropped to 13·5 per cent. A comparison of the percentage discrepancies obtained for the two structures is shown in Table 1.

Table 1. PERCENTAGE DISCREPANCIES OBTAINED FOR STRUCTURES) BASED ON THE ALTERNATIVE SPACE GROUPS $P2_1/a$ AND *Pa*

Space group	(*h*0*l*)	(*hk*0)	(0*kl*)	(*hkl*
$P2_1/a$	8·6	8·9	12·9	13·5
Pa	11·5	14·2	20·0	22·4

These figures establish definitely that azulene has a disordered structure as postulated earlier by Günthard[3]. This disorder is of the same type as found in *p*-chlorobromobenzene[4,5] and is also similar to that reported in the case of 2-amino-4-methyl-6-

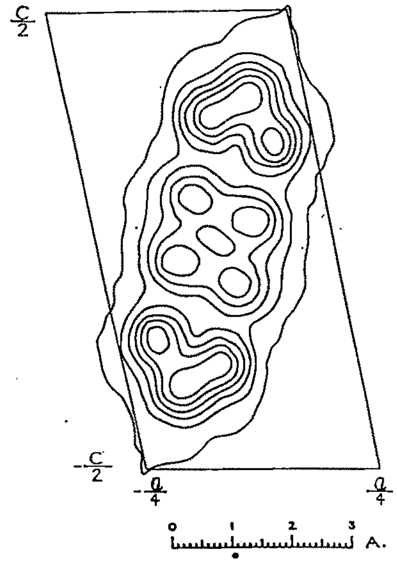

Fig. 2. Azulene. Electron-density projection on (010)

chloropyrimidine[6], though in these cases because of the symmetry of the molecules there are effectively only two atoms involved in the disorder—the chlorine and bromine atoms in the first case, and the chlorine atom and the methyl group in the second case.

An examination of the X-ray photographs showed no trace of additional layer lines and no diffuseness in the spectra, so that the possibility of a fault structure with blocks of the crystal containing molecules properly aligned in one direction and other blocks with molecules properly aligned in the other direction can be excluded. This is also the case with *p*-chlorobromobenzene and 2-amino-4-methyl-6-chloropyrimidine.

An electron-density projection on (010) for the revised structure is shown in Fig. 2. The similarity of this projection of a pair of statistically superimposed molecules to the electron-density projection given in our previous structure[1] is striking and explains the good structure-factor agreement obtained for that structure.

Because of the overlap of atoms the bond-lengths available from this study are of limited accuracy, but the central bond at 1·458 A. appears to be distinctly longer than the other bonds in the molecule. A more complete analysis of this structure will be described elsewhere.

Presence of 1,2,3,4-Dibenzopyrene in Cigarette Smoke

In an investigation of the neutral fraction of cigarette smoke tar for the presence of carcinogenic hydrocarbons[1], the fluorescence spectra given by various chromatographic fractions were obtained. One of these (spectrum *h*) has been found to be identical with the spectrum given by a sample of pure 1,2,3,4-dibenzopyrene, which has since become available for reference.

The fluorescence spectrum of the compound in cyclohexane consists of a series of fine lines at 462, 470 and 478 mμ, the latter being of lower intensity than the first two. The absorption spectrum of the analytical sample gave all the features of the reference standard[2]. The chromatographic behaviour of both standard and analytical samples on columns of alumina was similar, elution occurring after 3,4-benzopyrene but before 11,12-benzofluoranthene. The latter two compounds, organic solvent solutions of which display a blue–violet fluorescence, occur widely in the combustion products of organic matter. The 1,2,3,4-dibenzopyrene is associated with a light green fluorescence.

The 1,2,3,4-dibenzopyrene was estimated by measurements of the peak height at 331 mμ. 1·6 μgm. was recovered per 100 cigarettes of average weight 1·1 gm., smoked to a stub length of about 1·5 cm. This is of the same order of concentration as that found for 3,4-benzopyrene.

Small quantities of 1,2,3,4-dibenzopyrene have been detected in petrol and the exhaust products of Diesel engines. It has not, however, been detected in a sample of general urban atmospheric soot, in marked contrast to 3,4-benzopyrene, which was found to occur there in a relatively high concentration[3]. Thus, it would appear that the urban-dwelling cigarette smoker has an exposure to 1,2,3,4-dibenzopyrene in a concentration not realized by his non-smoking neighbour.

As a result of preliminary tests, Bachmann *et al.*[4] and Cook and Kennaway[5] have described 1,2,3,4-dibenzopyrene as a carcinogenic agent of considerable potency.

Radiometric Estimation of Unsaturated Fatty Acids on Chromatograms

A technique is desirable for estimating amounts of fatty acids separated by partition paper chromatography, without necessity for time-consuming elution, and free from inherent errors of strip photometry. Radiometric methods can meet these requirements, and in chromatographic applications have sometimes allowed accurate definition of spot geometry, which in some cases may be quantitatively related to spot content[1].

Kaufman[2] has determined the iodine number of unsaturated fats pipetted on to a paper support, using iodine-131 monobromide in absolute methanol. We have used iodine-131 to develop a method for quantitative estimation of unsaturated fatty acids separated by partition paper chromatography.

The acid mixture is revolved on 15 mm. × 280 mm. Schleicher and Schull 598 *L* paper strips, using a mixture of synthetic hydrocarbons of very low bromine number (0·16) and boiling point 180–190° C., called 'Mepasine' (Polish product, Ciech, Warsaw), as stationary phase, and 90 per cent acetic acid saturated with 'Mepasine' as mobile phase in ascending reversed-phase chromatography under nitrogen. 'Mepasine' is applied to the strips as a 20 per cent solution in freshly distilled ether free of peroxide, followed by evaporation of the ether.

The strip is dried after chromatography at 60° C. for 1 hr. in nitrogen. It is then immersed in 6·5 ml. of a solution of 0·0022 *M* sodium iodide, 0·0044 *M* sodium iodate, and containing about 5 μc./ml. iodine-131 as iodide. The solution is made 0·025 molar in sulphuric acid to liberate iodine. After immersion for 150 min., the strip is removed, and dried overnight at room temperature, during which time excess unbound iodine-131 is given off.

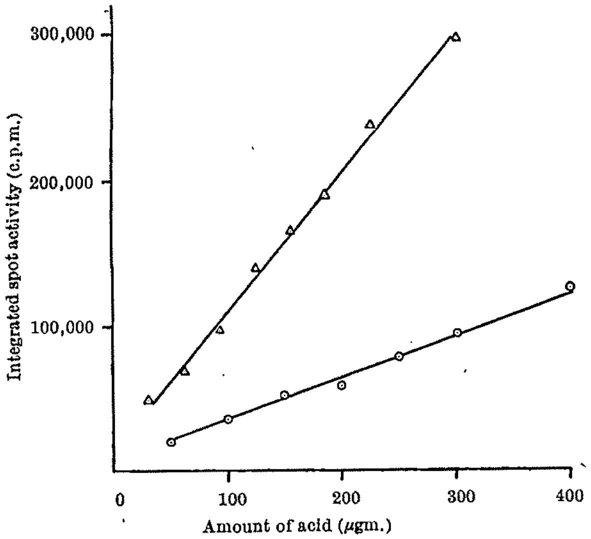

Fig. 1. Relation between integrated spot activity and spot content in chromatograms of oleic (⊙) and linoleic (△) acids iodinated with iodine-131

Distribution of β-activity is determined by drawing the strip in 2-mm. steps under a 2 mm. × 15 mm. slit in a 'Perspex' screen, 4 mm. thick, located under an end-window Geiger–Müller counter with a window thickness of 4 mgm./cm.[2].

Fig. 1 shows the relation between spot content and integrated total spot activity minus background activity of the paper. A satisfactory, reproducible, linear relation, indicating quantitative or reproducibly proportional iodination, is obtained for oleic and linoleic acids. The radiometric technique has also been used to determine spot length or maximum spot activity, in order to relate these to spot content. Maximal spot activity is defined in terms of β-activity counted through a 2 mm. × 15 mm. slit across the point of maximum activity in the spot, and is clearly related to maximum spot thickness. Linear relationships adequate for estimating spot content are also obtained between spot content and spot length, or between logarithm of spot content and maximum spot activity, for chromatograms of oleic and linoleic acids.

To take account of given experimental conditions a calibration line can be set up by chromatography of known amounts of pure oleic or linoleic acids alongside the fatty-acid mixture. Standards for this purpose can be prepared conveniently by chromatography of 200 mgm. of impure acids under nitrogen on paper strips 300 mm. wide, under the conditions described above, followed by elution from the appropriate bands cut from the paper and titration.

Linear relations between spot length and spot content have not so far been reported in paper chromatography of other substances, and no work seems to have been done on correlation of maximum spot thickness with spot content. In fact, apart from less reliable strip-photometry, radiometric estimation would seem to be the only way of measuring maximum spot thickness at present available.

For routine work this estimation procedure can be speeded up by measuring the background activity of the paper immediately before and after the spot, and taking two or three readings around the area of apparent maximum spot density to locate and measure the maximum spot activity, instead of taking the whole radiochromatogram. For this purpose, to locate the region of maximum spot density approximately, and to define the spot area roughly, a conventional visualization technique (such as use of copper ferrocyanide or rhodamine *B*) can be used in conjunction with the radiometric method.

Further studies are in progress to extend this work.

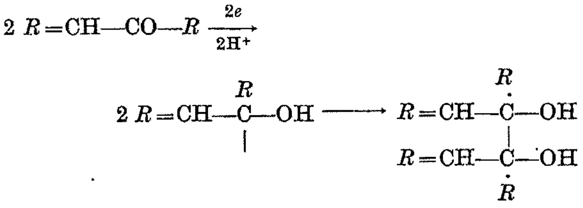
Half-wave Potentials of Aromatic Ketones

The unsaturated aromatic ketones undergo irreversible reduction at the dropping mercury electrode to give different products in acid and in alkaline media respectively. In the acid medium the reduction product is a dimeric alcohol, the formation of which may proceed through an intermediate free radical by the following mechanism:



$$2\,R{=}\mathrm{CH}\text{—}\mathrm{CO}\text{—}R \xrightarrow[2\mathrm{H}^+]{2e}$$

$$2\,R{=}\mathrm{CH}\text{—}\overset{R}{\underset{|}{\mathrm{C}}}\text{—}\mathrm{OH} \longrightarrow \begin{array}{l} R{=}\mathrm{CH}\text{—}\overset{R}{\mathrm{C}}\text{—}\mathrm{OH} \\ \qquad\qquad | \\ R{=}\mathrm{CH}\text{—}\underset{R}{\mathrm{C}}\text{—}\mathrm{OH} \end{array}$$

The half-wave potential ($E_{1/2}$) for the process is therefore associated with the addition of an electron and a proton to the oxygen atom, and according to the view advocated by us[1,2] the half-wave potential may be related to the O-localization energy. In order to test this hypothesis the O-localization energies, $L(-\beta)$, of benzaldehyde, benzophenone and dibenzalacetone have been calculated by the conventional molecular orbital method (taking the Coulomb integral for oxygen as $\alpha_c + 2\beta$ and for the carbon atom attached to oxygen as $\alpha_c + 0{\cdot}1\ \beta$, where α_c is the Coulomb integral for aromatic carbon and β is the resonance integral for the C—C bond) and are given in Table 1 along with the appropriate values for $E_{1/2}$. It is evident from Table 1 that as the localization energy increases, the half-wave potential also increases. In the case of acetophenone and benzalacetone, the presence of an electron-donating methyl group at the α-position with respect to the C=O group will increase the electron density at the bond, and consequently the energy necessary to add an electron to the oxygen atom in acetophenone will be greater than in benzaldehyde. In fact, in the acid region, the half-wave potential of acetophenone is higher than that of the benzaldehyde. The localization energy for acetophenone could be calculated by the molecular orbital method taking into consideration the hyperconjugation effect of the methyl group, but the calculation is so involved that it was not considered worth the trouble.

Table 1. Localization Energy and Half-wave Potentials for Aromatic Ketones

Compound	pH	$E_{1/2}$ (vs. S.C.E.)*	$L(-\beta)$	$E_M(a - a_c/\beta)$
Benzaldehyde	1·3	0·98	2·6900	0·1900
Benzophenone	1·3	0·94	2·5930	0·1450
Dibenzalacetone	1·3	0·90	2·5178	0·0836

* See ref. 4.

The last column of Table 1 gives the energy (E_M) of the first unoccupied molecular orbital, which according to Maccoll[3] should be related to the half-wave potential of the compound concerned. It is evident from Table 1 that Maccoll's suggestion is equally valid for the reduction of these ketones in the acid region.

In the alkaline region the double bond reduced depends on the nature of the compound. Thus benzophenone is reduced to the corresponding alcohol, whereas benzalacetone gives the corresponding saturated ketone. In one case the C=O bond is reduced, while in the other the C=C bond is reduced. These systems, therefore, cannot be compared by the localization method, although Maccoll's method of adding two electrons to the first empty level will still be valid.

Fluorescent Derivatives obtained by the Reaction of Ethylene Diamine with Epinephrine and Norepinephrine

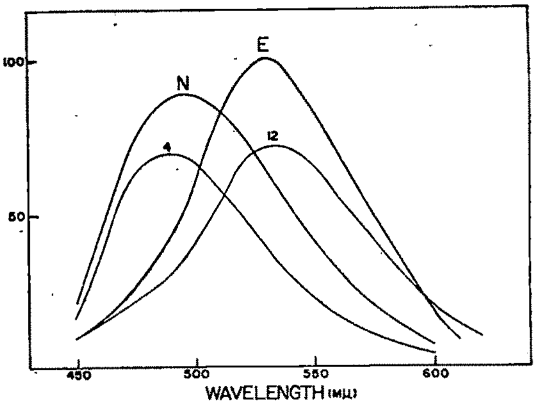

Fig. 2. Fluorescence spectra of *iso*-butanol extract from epinephrine (*E*), norepinephrine (*N*) and of various derivatives obtained after separation with paper chromatography. The numbers correspond to those of chromatogram *A* in Fig. 1. Relative height of peaks is not significant. (Excitation wave-length, 436 mμ)

In the analytical procedure[1-3] for catechol amines based upon their reaction with ethylene diamine, it is commonly assumed that both epinephrine and norepinephrine form a single fluorescent derivative respectively, although Burn and Field[4] have recently supported the existence, for each amine, of at least two fluorescent products. Gray and Young[5], on the other hand, have failed to demonstrate more than one derivative by means of paper chromatography.

Preliminary trials in this laboratory, with circular paper chromatography (using a highly retentive paper such as Schleicher and Schuell No. 576 and an *iso*-butanol/acetic acid/water developing solvent), gave some indication that the fluorescence obtained by the reaction of ethylene diamine on either catechol amine was due to several constituents rather than to a unique 'condensation' derivative. Further attempts to separate these constituents, either by ascending paper chromatography or by paper strip and curtain electrophoresis, were more or less successful until it was discovered that the large excess of ethylene diamine used for the reaction interfered with proper resolution. When electrophoretic separation on paper strips was then attempted on an *iso*-butanol extract obtained from the reaction with epinephrine, nine bands of fluorescent material were visible under optimum conditions (McIlvaine pH 8·0 buffer diluted 1 : 5 with water, 200 V., 20–25 m.amp. for 4 hr.). The same procedure applied to norepinephrine yielded eight distinct bands.

Better resolution was obtained by means of two-dimensional chromatography on paper, if the excess of ethylene diamine was eliminated either from the reaction mixture or its extracts. Development in a first direction with an aqueous phase (butanol-saturated phosphate buffer at pH 6·0) eliminated most of the unchanged epinephrine and the residual ethylene diamine, which both migrated rapidly, as compared with the other constituents of the mixture. A mixture of *n*-butanol/acetic acid (100 : 15) saturated with water was then used for development in the other direction. Fig. 1 illustrates two typical chromatograms obtained from epinephrine and norepinephrine respectively. The identity of various spots with epinephrine

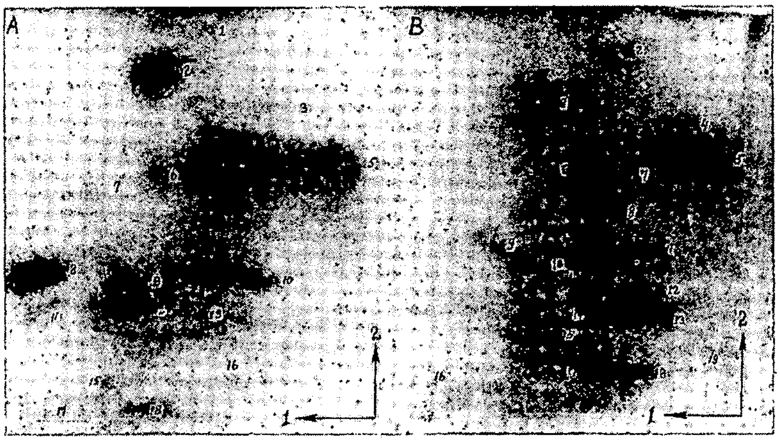

Fig. 1. Two-dimensional chromatograms obtained from epinephrine (*A*) and norepinephrine (*B*), after reaction with ethylene diamine (*iso*butanol extract). Spot Nos. 1, 2, 4, 5, 6, 8, 9, 10, 12 and 16 in chromatogram *A* correspond to radioactive areas obtained from β-^{14}C-DL-epinephrine

derivatives was confirmed by duplicating the procedure with epinephrine labelled with carbon-14. Localization of radioactive areas was obtained by placing the chromatograms in contact with Ilford 'No-Screen' or Kodak 'Blue Brand' medical X-ray films for several weeks.

The spot located at approximately R_F 0·58–0·61 (first dimension) and R_F 0·29–0·35, identified as No. 12 in chromatogram *A* (Fig. 1), gives an intense yellow fluorescence under ultra-violet light and forms one of the major constituents of the reaction mixture. Its fluorescence spectrum is compared in Fig. 2 with those of some secondary products and of the total extractable fluorescence obtained according to the procedure described by Weil-Malherbe and Bone[2]. Fluorescence spectra were obtained with the aid of a Beckman 'Model *B*' spectrophotometer modified by us for that purpose[6].

A Simple and Rapid Method for the Biological Assay of Glucocorticoids

IT has been well established that adrenocortical steroids have a pronounced effect on carbohydrate metabolism, in particular on the level of liver glycogen. Various methods for the assay of adrenocorticoids have been reported[1,2], based upon the ability of these substances to cause a deposition of glycogen in the livers of adrenalectomized rats and mice. However, all these methods appear to be sufficiently complex and tedious to exclude their use when rapid screening procedures are desired. Van der Vies[3] has described two colorimetric methods for the determination of glycogen in body tissues.

In a series of experiments on mice, by modifying the method of Venning, Kazmin and Bell[2], and employing a modification of one of the methods of van der Vies[3], we have produced a simple, rapid, yet highly sensitive method of assaying the glucocorticoid effect of some adrenal steroids.

Male white mice (13–15 gm.) of the Swiss strain produced by the Agricultural Research Council were used in all experiments. The mice are adrenalectomized under ether anæsthesia and maintained on a cube diet (M.R.C. 41*b*) with normal saline for drinking. On the evening of the first post-operative day food is withdrawn and the mice fasted until the following morning. On the morning of the second post-operative day the mice are divided at random into groups of ten and injected intramuscularly with the steroid or test material. Three hours after treatment the animals are weighed as a group, killed by stretching the necks, and their livers extirpated. The whole livers of all the mice in a group are transferred as quickly as possible into 100 ml. of a 5 per cent solution of trichloracetic acid and homogenized or ground with sand in a mortar. The homogenate is filtered under reduced pressure through a Whatman No. 54 paper. A sample of 2 ml. of the filtrate is taken and added to 2 ml. of 10 *N* solution of potassium hydroxide in a boiling-tube. The solution is heated for one hour in a boiling water-bath and then cooled; 1 ml. of glacial acetic acid and 5 ml. distilled water are added. After mixing, 2 ml. of this solution is slowly added to 4 ml. of freshly prepared anthrone reagent (0·2 per cent anthrone in 95 per cent sulphuric acid) in a boiling-tube which is placed in iced water to prevent excessive heating. The solutions are mixed by lateral shaking and placed in a boiling water-bath for exactly 10 min. for colour development, and cooled with tap-water. The extinction is read within 2 hr. in an absorptiometer at 650 mμ against a blank prepared by submitting 2 ml. trichloracetic acid to the same procedure as that described for the liver homogenate. The glucose standards for the calibration curves are prepared by heating three quantities of 2 ml. trichloracetic acid and 2 ml. potassium hydroxide in a water-bath as described above, then adding 1 ml. glacial acetic acid followed by 0·5-ml., 1·0-ml., or 2·0-ml. samples of a 1 mgm./ml. solution of glucose in distilled water. After the addition of 4·5 ml., 4·0 ml. and 3·0 ml. of distilled water, respectively, the procedure is continued in the usual way.

The result is expressed in terms of mgm. liver glycogen equivalent per 100 gm. mouse body-weight.

Venning and her associates[2] demonstrated that specific quantities of glucose administered together with the steroid provoked a striking increase in liver glycogen deposition, although the increase caused by the same dose of glucose administered alone was not significant. In this present study preliminary experiments have corroborated this finding (Fig. 1). These results indicate that doses of either 10 mgm. or 20 mgm. glucose per mouse, incorporated into the injection solution, greatly increase the response to a given dose of cortisone acetate, without themselves

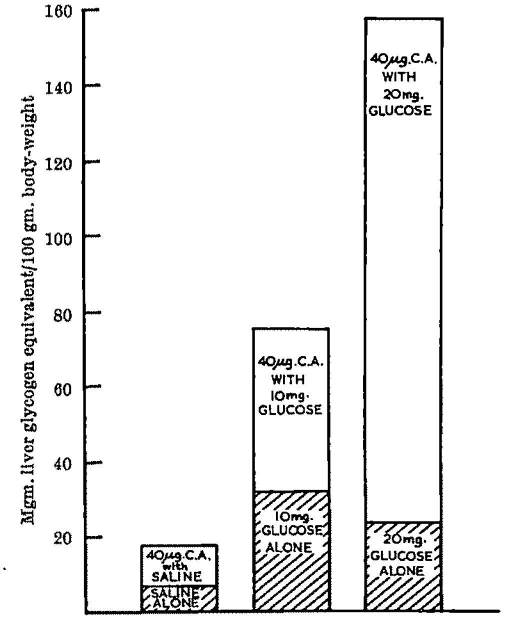

Fig. 1. The effect of glucose, incorporated into the injection solution, on the response produced by a standard dose of cortisone acetate*

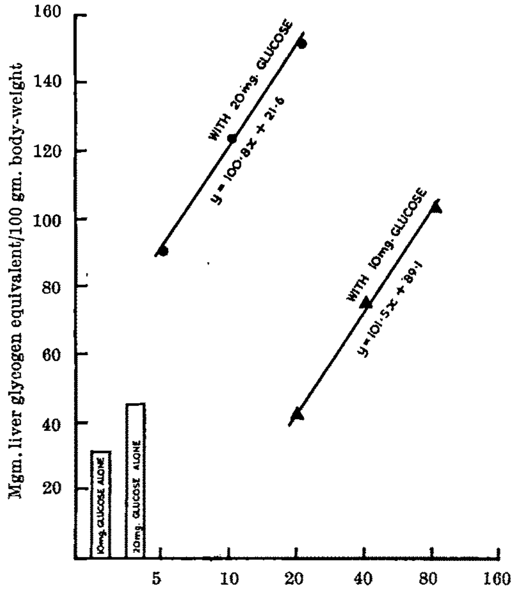

Fig. 2. The effect of glucose, incorporated into the injection solution, in enhancing the sensitivity of the assay method to cortisone acetate

having any pronounced effect on the level of glycogen in the liver. However, further experiments have shown that doses of glucose greater than 20 mgm. per mouse cause deposition of glycogen in the liver. In agreement with the findings of other workers[2] these studies have also shown that there is considerable variation in the liver glycogen response to injected glucose between different strains of mice. Further investigations have shown that the range of sensitivity of the method to adrenal steroids can alter accordingly to the amount of glucose injected with the steroid (Fig. 2). A dose of 10 mgm. glucose injected with the steroid produced a range of sensitivity of 20–80 μgm. of cortisone acetate, whereas with a dose of 20 mgm. the sensitivity was increased to a range of 5–20 μgm. of cortisone acetate.

The assay method has proved to be simple, rapid and highly sensitive. The practice of estimating the glycogen-level of the bulked livers of a group of mice does not enable information to be calculated concerning the scatter in the individual responses within each dosage group. However, it is considered that the method of assay described is well suited to the routine examination of synthesized compounds for glucocorticoid activity.

We should like to express our appreciation to Prof. G. A. H. Buttle, for his helpful advice and interest in this work.

5-Hydroxytryptamine and Hyperglycæmia

It has been suggested that the hyperglycæmic substance present in the blood of the pancreatico-duodenal vein of animals treated with the growth hormone of the pituitary gland is 5-hydroxytryptamine[1]. This amine may be derived from the enterochromaffin or other cells of the gastrointestinal tract. Yet injections of 5-hydroxytryptamine into normal dogs fail to produce a significant rise in blood sugar, although similar injections into depancreatized animals result in hyperglycæmia. Thus the pancreas may be responsible for the inactivation of 5-hydroxytryptamine.

Recently I have been studying the distribution of 5-hydroxytryptophan decarboxylase, an enzyme forming 5-hydroxytryptamine from 5-hydroxytryptophan, and I was surprised to find that the pancreas possesses a considerable degree of enzyme activity. For example, homogenates of the pancreas of the rat, guinea pig, rabbit, cat and dog all possessed activity, 1 gm. of tissue forming 19–55 μgm. of 5-hydroxytryptamine in 60 min. For comparison, the richest source of the enzyme, namely the kidney, formed 47–188 μgm. of 5-hydroxytryptamine/gm. of tissue. The method of Gaddum and Giarman[2] was followed using 4×10^{-4} *M* substrate, but in place of the choline *p*-tolyl ether I used iproniazid as the inhibitor of monoamine oxidase. When 5-hydroxytryptamine was used as the substrate and iproniazid was omitted from the reaction mixture, it was possible to estimate the monoamine oxidase activity of the homogenates. This showed that 1 gm. of pancreas deaminated 1·2–2·4 μgm. of 5-hydroxytryptamine in 60 min., whereas 1 gm. of kidney inactivated about 8 μgm. of the amine when tested by this method.

The pancreas has not so far been considered as a source of 5-hydroxytryptamine. The present results show that it possesses not only much 5-hydroxytryptophan decarboxylase activity but also monoamine oxidase activity. This latter finding probably explains why the 5-hydroxytryptamine content of the pancreas of the species tested is so low (0·05–0·1 μgm./gm.). It should now be possible to identify the hyperglycæmic substance in the pancreatico-duodenal blood after injections of growth hormone, and to test its action on the blood sugar of animals treated with monoamine oxidase inhibitors such as iproniazid or choline *p*-tolyl ether.

A Yellow Fluorescent Pigment in Elastin

Mainly due to the pioneer work of Szent-Györgyi[1] it is known that a close relationship may exist between the fluorescence of a certain compound and its activity in energy transfer and thus in metabolism. This suggests that the strong fluorescence of elastin[2], until recently regarded as an inert protein of only structural significance, may be important.

The cause of this fluorescence has not been established. With[3] suggested the presence of firmly bound pigments originating from porphyrin in elastin, and Partridge and Davis[4] found a yellow pigment in their elastin hydrolysates. Labella[5] was the first to postulate a metabolic function for elastin, suggesting that the presence of an unsaturated lipid is necessary to maintain the particular structure of the elastin molecule. The occurrence of a strong fluorescence was not noticed by the latter authors.

I prepared elastin from ligamentum nuchæ of cattle according to Partridge *et al.*[6]. Partial hydrolysis by activated papain followed by dialysis yielded a clear, bright yellow solution with a yellowish-white fluorescence. Paper chromatography (Whatman 1 or 3 *MM* paper, *n*-butanol/ethanol/0·5 *M* ammonia (70 : 10 : 20) (v/v)) showed a bright fluorescent spot with R_F 0·86, but most of the yellow pigment remained bound to polypeptide residues, as was indicated by subsequent paper chromatography after hydrolysis with hydrochloric acid.

Milligram amounts of the pigment were prepared by hydrolysis with hydrochloric acid. 15 gm. of dry elastin powder were hydrolysed with 600 ml. of 6 *N* hydrochloric acid by refluxing for 24 hr., the hydrochloric acid was removed (by evaporation under reduced pressure in an atmosphere of nitrogen) and the yellow pigments adsorbed on charcoal. The pigments were eluted with hot pyridine, the pyridine was removed completely and the dry residue extracted with dry peroxide-free ether. This solution was washed with 2 per cent sodium bicarbonate and then with a 2 per cent sodium hydroxide solution to extract fluorescent impurities which originate from the action of hydrochloric acid on amino-acids. The pigment was purified by large-scale paper chromatography on Whatman 3 *MM* paper.

A number of properties of the pigment have been determined by chromatography in various solvents, spectrophotometry and chemical spot tests[7].

The pigment is insoluble in water and petroleum ether, but soluble in methanol, ether and chloroform. The absorption spectrum (Fig. 1) shows two distinct absorption maxima, almost independent of the *p*H of the solvent. The R_F value (0·85–0·88) is not altered by substituting acetic acid for the ammonia in the solvent, which also shows that the compound has no distinct acidic or basic properties.

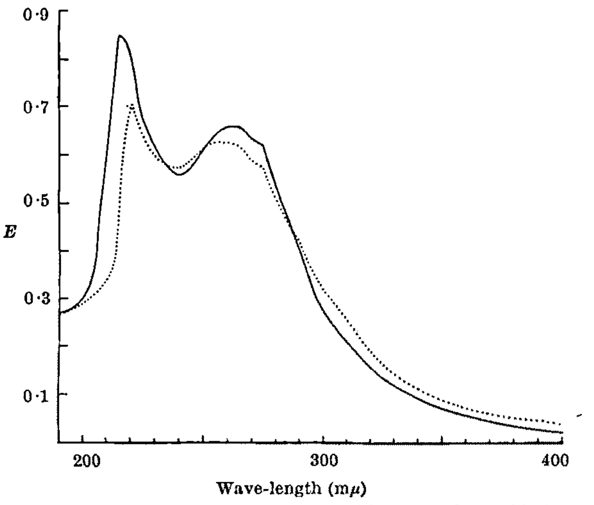

Fig. 1. Absorption spectrum of pigment in 0·01 *N* hydrochloric acid in absolute ethanol (——) and in the same concentration in 0·01 *N* potassium hydroxide in absolute ethanol (- - -)

The presence of the elements carbon, hydrogen and nitrogen was shown, the nitrogen probably being present as a tertiary amine. Oxidation with nitric acid shows the formation of polynitro compounds and the appearance of a carboxylic acid. Spray reagents on paper revealed aromatic hydroxyl groups and a positive Ehrlich diazo reaction. Tests for pyrrole were negative.

Preparation of a larger amount of pigment allows a more exact examination of its properties. These results suggest a structure related to the pyrimidines, purines or pteridines.

Differential Demonstration of Acetylcholinesterase and Non-specific Cholinesterase in the Adrenal Medulla of the Rat

Using naphthyl acetates as substrates, Coutinho *et al.*[1] demonstrated histochemically that adreno-medullary cells of the rat can be divided into two categories, esterase-positive and esterase-negative. Allen, Eränkö and Hunter[2] confirmed this observation and showed that the regions of those medullary cells which fluoresce in ultra-violet light after fixation in calcium formol and which presumably contain noradrenaline[3] were strongly cholinesterase-positive, while the remaining parenchyma was weakly positive or negative. After studies with some inhibitors they also suggested that two or more types of cholinesterases are involved in the histochemical reactions.

The nature of the adreno-medullary cholinesterases has been further studied by using 62.*C*.47 (1 : 5-*bis*-(4-trimethylammonium-phenyl)pentan-3-one di-iodide), a specific inhibitor of acetylcholinesterase, and tetra-*iso*propylpyrophosphoramide, a specific inhibitor of non-specific cholinesterase[4]. Acetylcholinesterase was demonstrated using Koelle's[5] improved method. Into the prescribed substrate mixture containing acetylthiocholine, however, tetra-*iso*propylpyrophosphoramide was added in a molar concentration of 10^{-6}. For the demonstration of non-specific cholinesterase, acetylthiocholine was replaced by butyrylthiocholine and 62.*C*.47 was used instead of tetra-*iso*propylpyrophosphoramide in a molar concentration of 10^{-5}. Naphthyl acetate was also used as a substrate.

Sections incubated in solutions of acetylthiocholine and tetra-*iso*propylpyrophosphoramide showed a positive reaction in the ganglion cells, the nerve trunks and a network of fine fibres surrounding all parenchymal cell groups. In the fine nerve net, small knobs were strongly positive. After incubation in butyrylthiocholine and 62.*C*.47, ganglion cells and nerve trunks were again strongly stained. On the other hand, the main bulk of the medullary parenchyma was essentially negative except for groups of parenchymal cells forming small islets, which were surrounded by a network of strongly positive fibres. Incubation with butyrylthiocholine or with α-naphthyl acetate produced identical results with or without 62.*C*.47. Eserine and tetra-*iso*propylpyrophosphoramide (10^{-6} *M*) inhibited the medullary reaction with these substrates.

Since the reaction worked equally well with fresh-frozen and with calcium formol-fixed sections, it was possible to register photographically, first the distribution of the calcium formol-induced fluorescence, and then that of the cholinesterases. It was thus proved that the regions of the fluorescent cell groups showed a high, the non-fluorescent parenchyma a low, activity of non-specific cholinesterase.

Non-specific cholinesterase can be demonstrated in a specific way with butyrylthiocholine even without 62.*C*.47. This was done, the section was photographed, incubated with acetylthiocholine and 10^{-6} *M* tetra-*iso*propylpyrophosphoramide to detect acetylcholinesterase, and photographed again. Comparison of the pairs of photographs thus obtained confirms very clearly the different distributions of acetylcholinesterase and the non-specific esterase in a single section. Similar differentiation could not be obtained using di-*iso*propylfluorophosphate, which has commonly been used to inhibit non-specific cholinesterase[5].

Denervation of the adrenals was followed by a total disappearance of acetylcholinesterase from the medulla, except for the cytoplasm of some ganglion cells, but did not affect the distribution of non-specific cholinesterase in the fluorescent parenchyma. Prolonged treatment with nicotine, on the other hand, resulted in an increase in the intensity of the non-specific cholinesterase reaction, and the reaction was more widely spread in the medulla than normally.

These results justify the conclusion that there are in the adrenal medulla of the rat two types of cholinesterases, which behave differently towards different substrates and different inhibitors. Of these the type which is sensitive to 62.*C*.47 and which disappears after denervation is apparently a specific acetylcholinesterase coupled to the mechanism of nervous transmission. The other enzyme, which is sensitive to tetra-*iso*propylpyrophosphoramide, affected by treatment with nicotine and selectively localized in the regions of the parenchymal cells containing noradrenaline, may be connected with the metabolic processes of these parenchymal cells.

Further details of the methods and results will be published elsewhere.

This work has been supported by a research grant from the National Institute of Arthritis and Metabolic Diseases, U.S. Public Health Service (*A*–1725). Samples of 62.*C*.47 were obtained through the courtesy of Dr. F. C. Copp, The Wellcome Research Laboratories, tetra - *iso*propylpyrophosphoramide through the courtesy of Messrs. L. Light and Co., Ltd.

Agar Electrophoretic Patterns of Red Blood Cell Proteins

IT has been previously reported from this laboratory that both animal (rat)[1,2] and human[3] red blood cell hæmolysates show the presence of minor protein components other than hæmoglobin after electrophoresis in agar gel medium. Because of their possible interaction with hæmoglobin molecules in the red cell and their variation in hæmatological disorders and other pathological conditions, more detailed study of these proteins appeared of interest.

Stern *et al.*[4], in a preliminary study, demonstrated the presence of proteins other than hæmoglobin by moving-boundary electrophoresis. The hæmolysates examined (man, dog and chicken) showed the presence of a small amount of an opalescent, colourless fraction (protein *a*) with anodic mobility (at *p*H 8·6) twice as high as that of oxyhæmoglobin. This protein component was assumed to be derived from the membrane or stroma of the cells. In addition to this component, human and dog hæmolysates were found to contain another colourless component (protein *b*) with a mobility smaller than that of hæmoglobin, while chicken red cell hæmolysate was found to contain a component (protein *c*) with a mobility intermediate between that of hæmoglobin and protein *a*. Hoch[5] reported the occurrence of two components faster than the oxyhæmoglobin in fresh red-cell extracts.

The minor protein patterns observed by the agar electrophoresis technique showed marked difference from the moving boundary patterns obtained by Stern *et al.* and Hoch. At least three minor protein components, in addition to hæmoglobin, are present in human red blood cell hæmolysates, with mobilities lower than that of hæmoglobin, and no fast-moving component (protein *a*) was observed.

The method of separation of these proteins by agar electrophoresis followed the procedure presented previously, except that higher concentration of the hæmolysate was used to reveal the minor protein components, some of which will not be visible at the low concentrations used in previous experiments reported earlier. After electrophoresis, the proteins were stained with amido black 10*B* [6].

Fig. 1 is a typical pattern showing the minor protein components and the hæmoglobin in human red-cell hæmolysate. The red cells were washed six times with 0·9 per cent sodium chloride before hæmolysis.

Hæmolysates from more than twelve samples of human blood examined by this method always gave the same result. Separation of three protein components was, therefore, reproducible. For convenience the protein components are designated RP_1, RP_2 and RP_3 with decreasing order of mobility. RP_1 and RP_2 occur in high concentration compared to RP_3. Occasionally the RP_1 component merged with the hæmoglobin band. The protein components did not give any positive reaction with benzidine reagent, fuchsin sulphite after periodate oxidation or sudan black, thereby showing that they are not hæmoglobins and they do not contain carbohydrate or lipid materials. The electrophoretic behaviour of the protein components (compactness of the bands and the difference between their mobilities and those of serum proteins) indicates that they are the intracellular proteins of the red cell and not serum proteins. A comparative study of the electrophoretic patterns of human serum proteins and hæmolysates obtained on the same plate showed that the mobility of RP_3

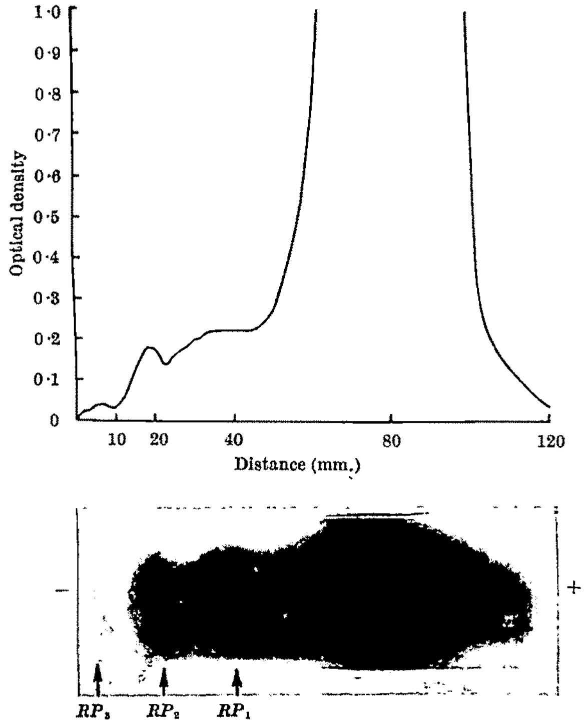

Fig. 1. Agar electrophoretic pattern of human red blood cell proteins. (8·6 *p*H ; 200 V., 8 m.amp., 10 hr. run, 80 μl. of hæmolysate applied on the gel)

approached that of γ-globulin, while RP_1 and RP_2 possessed mobilities between those of γ- and β-globulins of serum. The relative amounts of RP_1, RP_2 and RP_3 as determined from the areas of the peaks obtained by densitometric measurement are approximately 40, 46 and 14 respectively (excluding hæmoglobin). Animal red blood cells (rat and sheep) also contain these proteins to a varying degree. It will be of interest to investigate the variation of these proteins in red blood cells under pathological conditions and their significance in relation to hæmoglobins, and sickling phenomena and allied hæmatological disorders.

Pre-requisites for Dextran Production by *Streptococcus bovis*

In a recent paper[1] we showed that many strains of *Streptococcus bovis* of rumen origin gave good yields of an unbranched dextran when incubated anaerobically for one day at 38° C. in a liquid sucrose medium. An essential condition for these yields of dextran was either incubation in a 100 per cent carbon dioxide atmosphere or the incorporation of solid calcium carbonate or 0·01 *M* bicarbonate in the medium. The latter was well buffered with 0·05 *M* phosphate and also contained 0·5 per cent yeast extract and 1·1 per cent casitone, or an equivalent peptone as sources of organic nitrogen, and growth factors. In the absence of carbon dioxide, cell yields were almost as good as in its presence and, though a normal lactic acid fermentation took place, little or no dextran was produced. No detailed study of the effect of buffer strength and composition on dextran yields nor any attempt to simplify the medium was made at the time.

We now find that :

(*a*) Adequate buffering of the medium is a prerequisite for high dextran yields. Reducing the phosphate to a level (0·01 *M*) which was still adequate for good growth and fermentation, almost completely stopped production of dextran even though carbon dioxide was supplied. As found by Whiteside-Carlson and Carlson[2] with *Leuconostoc*, phosphate could, with advantage, be replaced by acetate, since the latter can be used at a much higher concentration than phosphate (up to 0·25 *M*) without affecting growth. The effect of acetate concentration (in the presence of bicarbonate ion) on the conversion of sucrose to dextran and free fructose by *S. bovis* is shown in Table 1. High yields of dextran and of free fructose can be obtained after incubation for only 24 hr. at 38° C. without any external neutralization of the culture. Acetate can be replaced by propionate or butyrate or even by salts of organic acids of much lower pK_a values, such as lactic and formic acids. In these later cases the dextran yield is lower than with acetate of equivalent concentration.

(*b*) A carbohydrate and protein-free basal medium suitable for dextran production was devised by replacing the casitone and yeast extract by acid-hydrolysed casein and a mixture of B vitamins and growth substances similar to those used for *Leuconostoc* by Whiteside-Carlson and Carlson[4]. According to Ford, Perry and Briggs[5], *S. bovis* requires no B vitamins for anaerobic growth ; nevertheless we have clear evidence that pantothenic acid is absolutely necessary for the anaerobic production of dextran. Unlike *Leuconostoc*, however, *S. bovis* still requires carbon dioxide and a buffer in conjunction with this simplified medium for production of dextran to occur.

(*c*) Carbon dioxide gas in solution and not the bicarbonate ion is the first essential requirement for production of dextran. This follows from the following observations relating to sucrose cultures of *S. bovis* containing the correct phosphate *and bicarbonate*

Table 1. Effect of Acetate Buffer on the Conversion of Sucrose to Dextran, Fructose and Leucrose by *S. bovis* (Strain 1)

Acetate (*M*)	Dextran (percentage conversion of available glucose)	Free fructose (percentage of available fructose)	Leucrose (percentage of available sucrose)	Residual sucrose (by paper chromatography)
(1) Medium 0·5 per cent 'Bacto' yeast extract, 1·4 per cent 'Bacto'-tryptose, 8·5 per cent (w/v) sucrose and 0·004 *M* potassium carbonate (sterilized separately) ; 24-hr. incubation at 38° C.

concentrations for production of dextran, through which a slow, oxygen-free, stream of hydrogen was bubbled at 38° C. for 24 hr. (1) The organism would not grow at all if the hydrogen stream was free from carbon dioxide. (2) There was fair growth without formation of dextran if the hydrogen was first bubbled through 0·5 per cent sodium bicarbonate solution at room temperature to supply a trace of carbon dioxide, since bicarbonate solutions tend to revert to carbonate with loss of carbon dioxide even at room temperature. (3) There was good growth and good formation of dextran with conditions exactly similar to (2), except that the hydrogen was bubbled through saturated (10 per cent) sodium bicarbonate solution. We conclude that the concentration of carbon dioxide in solution needed for production of dextran is much higher than that essential for growth. The bicarbonate may function merely as a source of carbon dioxide at low *p*H values brought about by production of lactic acid rather than as the ion itself. In contrast, *Leuconostoc mesenteroides* still grew and produced dextran even when a stream of hydrogen free from both oxygen and carbon dioxide was bubbled through the sucrose medium at 28° C.

Not all rumen strains of *S. bovis* behave similarly, but even those strains that do not appear to have a definite need for carbon dioxide for slight production of dextran nevertheless require good buffering of the medium for production of dextran to occur. Temperature is a factor of importance in certain cases. We have one strain which appears to need carbon dioxide for formation of dextran at 38° but not at 28° C. Other strains behave similarly at both temperatures, except that growth is necessarily slower at 28° C. The organism will also grow at 47° C. in the presence of bicarbonate and high phosphate buffering, but no dextran is produced.

In contrast to *Leuconostoc*, the dextran formed at 28° C. is also unbranched. Addition of 0·008 *M* magnesium ion to the acetate-buffered medium, although resulting in only a trace of precipitate on autoclaving, did not produce branching in the *S. bovis* dextran at either 28° or 38° C. (cf. ref. 6).

As with *Leuconostoc*, good yields of dextran can be obtained only in sucrose media. A point of considerable importance, however, is that the specific soluble enzyme concerned (which appears to act as a dextransucrase; cf. ref. 7) is produced quite prolifically, by *S. bovis* at least, in a glucose liquid medium (particularly if it contains a mere trace of sucrose) as well as in a sucrose liquid medium. The enzyme was produced even when the culture used for inoculation had been carried through five successive tubes of glucose liquid medium and hence contained no trace of sucrose or apparently of dextran. The dextransucrase of *S. bovis* therefore appears to be constitutive rather than adaptive. Karström[8] long ago asserted that the *Leuconostoc* (*Betacoccus arabinosaceous*) enzyme system for dealing with sucrose was constitutive and not adaptive. However, he grew the organism at 37° C. and carried out his experiments with the washed cells in non-nutrient media at 45° C. It is unlikely, therefore, that he was studying *Leuconostoc* dextransucrase, which is mostly secreted extracellularly and is unstable at these temperatures[7]. Actually he had previously stated[9] that the sucrase of *Leuconostoc* is a glucosucrase; no mention was made of dextran as a product. The question of the adaptive or constitutive nature of *Leuconostoc* dextransucrase appears to be worth re-investigating.

The essential difference between *Leuconostoc* and *S. bovis* is that the former produces its own carbon dioxide (presumably within the cell) and acetate by sugar fermentation, whereas the latter produces only lactate—not a good buffer for dextran formation (see above)—without carbon dioxide. These deficiencies (namely, carbon dioxide and acetate or equivalent buffer) have apparently to be made good in the nutrient medium itself if dextran formation is to occur. So far as the production of the unbranched dextran is concerned, there is no need at this stage to postulate different mechanisms for *Leuconostoc* on one hand and *S. bovis* on the other.

This work on enzymes will be reported in full elsewhere by one of us (R. W. B.).

Content of Citrulline and Other Amino-Acids in a Protein of Hair Follicles

CITRULLINE has been shown to occur in the fibrous protein of the inner root sheaths of hair follicles[1]. This appears to be the first recorded occurrence of citrulline in an animal protein, although Smith and Young[2] described its presence in the protein of the red alga, *Chondrus crispus*.

In view of the unexpected occurrence of citrulline, it was of interest to investigate the quantitative composition of the protein of the inner root sheath and to compare it with the composition of the hair with which it is associated in the follicle.

Samples of inner root sheaths, hair roots and of the hairs themselves were prepared from vibrissa follicles of the rat[1]. They were dried in vacuum at 60° C. over phosphorus pentoxide and hydrolysed in sealed tubes for 10 hr. at 105° C. with constant-boiling hydrochloric acid, and subjected to quantitative amino-acid analysis by the ion-exchange chromatographic technique of Moore and Stein[3,4] as modified in this laboratory[5].

Because of the difficulty of obtaining sufficient inner root sheath and hair root material only single analyses were possible and the total nitrogen contents were not estimated. The analytical results could be expressed only as per cent dry weight (Table 1).

Control runs of authentic samples of *l*-citrulline and *l*-ornithine confirmed the identity of the peaks of these two amino-acids with those obtained in the analytical runs.

The analytical figure for citrulline confirms the earlier evidence that this amino-acid is a major component of the protein of the inner root sheath. However, the value reported is probably low because some of the citrulline is destroyed during hydrolysis

Table 1. AMINO-ACID COMPOSITION OF HYDROLYSATES OF HAIRS, HAIR ROOTS AND INNER ROOT SHEATHS FROM VIBRISSA FOLLICLES OF THE RAT

Per cent by weight of sample dried at 60° C. over phosphorus pentoxide

Amino-acid	Hair	Hair roots	Inner root sheath
Alanine	3·5	3·2	3·1

	83·9‡	74·6‡	70·0‡

* This must be regarded as a minimum figure since the optical density exceeded the limit for accurate reading by the equipment.

† Including ornithine produced from citrulline breakdown.

‡ The recoveries are all low. The analyses do not include tryptophan and proline, and have not been corrected for material not containing protein, such as pigment, nucleic acids, lipids and carbohydrates which are present to an unknown extent.

with the production of ornithine[1], a fact overlooked by Smith and Young, who used longer hydrolysis times in their analysis of *C. crispus*. It was unfortunate that in the present analysis ornithine was not resolved from lysine, and hence the citrulline and lysine contents could not be corrected. The low amide and small lysine plus ornithine figures suggest that this correction is not large.

Comparison of the analytical results shows that the fibrous protein of the sheath contains very little cystine, although methionine is present in greater amount than in hair. Of interest are the low arginine content and the extraordinarily high glutamic acid concentration in comparison with the values for hair, aspartic and glutamic acids together constituting more than 26 per cent of the protein. The low amide content implies that few carboxyl side-chains are amidated. Despite the lack of disulphide bonds compared with hair keratin, the protein of the sheath is not dispersed at alkaline *p*H values or by concentrated urea solutions[1]. If secondary forces are held responsible for this stability, these might be found in the increased possibilities for the formation of strong salt links and hydrogen bonds due to the high concentration of polar side-chains and to citrulline, which itself is a substituted urea.

Although the significance of citrulline in follicle metabolism is unexplained, it has been suggested[1] that the protein of the sheath provides ammonia to the growing hair for amidation of the side-chain carboxyl groups. Thus with the appropriate enzyme system present in the follicle, some arginine side-chains could be de-imidated to citrulline and ammonia. An enzyme system of this type has been described in extracts from crayfish muscle[6]. The amino-acid composition of the protein, in particular the low arginine and amide content, despite a high concentration of dicarboxylic amino-acids, and the high content of citrulline are in accord with this suggestion.

Comparison of the composition of hair roots with that of hair (Table 1) shows that the amide contents are similar, and so also are the amino-acid contents, excepting cystine, which is considerably lower in hair roots. This is in accord with the general view that the final cystine content of hair is established at a late stage in keratinization.

The technical assistance of Miss C. Potter and Miss M. T. McShane is gratefully acknowledged.

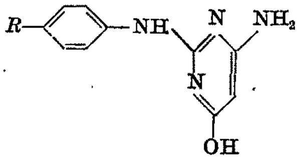
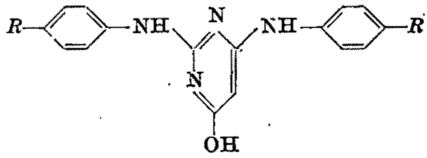
Arylaminopyrimidines as Growth-Inhibitors of *Streptococcus faecalis* and *Lactobacillus arabinosus*

IT has been found by Hitchings *et al.*[1] that 2 : 4-diamino-6-alkylpyrimidines which have bulky substituents (for example, phenyl) at C_5 are strong folic acid antagonists, some of which have marked antimalarial[2] and antileukæmic properties[3]. Furthermore, Curd, Rose and their co-workers had shown previously that many 6-alkylpyrimidines having substituted amino-groups at C_2 and C_4 were active as antimalarials[4].

In continuation of our studies of pyrimidines of potential chemotherapeutic interest, we have prepared several 2-arylamino-4-amino- and 2 : 4-diarylamino - 6 - hydroxypyrimidines (types I and II respectively) (methods of synthesis will be described elsewhere).



(I)



(II)

As shown in Table 1, these substances, particularly the di-arylamino compounds (II), caused marked inhibition of growth of *Streptococcus faecalis* and *Lactobacillus arabinosus*. However, these compounds differ from the parent member of the series, namely,

Table 1. INHIBITION OF *S. faecalis* and *L. arabinosus* BY ARYLAMINO-PYRIMIDINES

Compound	*S. faecalis**‡ Conc. (μgm./ml.) for 50 per cent growth inhibition	*L. arabinosus*†‡ Conc. (μgm./ml.) for 50 per cent growth inhibition

Effect of Monovalent Cations on Type Specificity Transformation in Pneumococci

FOR investigating the mechanism of bacterial transformation we have chosen as the experimental model the transformation of the *R* form of *Diplococcus pneumoniae* type II into the mucous form of *D. pneumoniae* type III, by means of crude extracts of deoxyribonucleic acid, isolated from the mucous form of *D. pneumoniae* type III. Systematic study was hampered by considerable variability in the results and by the low incidence of transformation in the control tubes.

Alexander *et al.*[1], working with *H. influenzae*, found that susceptible cells emerged at the end of the logarithmic period and at the beginning of the stationary phase of the growth-cycle when the density of the cell population was 2 to 4 × 10^8 cells per ml. The appearance of sensitive cells was lowest during the early logarithmic phase. Another important factor influencing the number of cells capable of transformation is the concentration of deoxyribonucleic acid (up to 10^{-1} μgm. per ml.). In practice, when all the above factors are present, only about 1 per cent of the *Haemophilus* recipient population undergoes transformation. In the case of pneumococci[2], 0·2–5 per cent of the exposed population was transformed.

Serum factors, which are necessary in the transformation of types of pneumococci, have been studied in detail[3-6].

Fox[7], without giving any particular details, describes the effect of calcium ions on the increase in the number of transformed cells during transformation of resistance in pneumococci.

In our experiments we were concerned mainly with the problem of how to eliminate variability of the transformation results with the *R* strain in question, with the question of the causes of this variability and with the possibility of increasing the number of *R* cells capable of transformation.

The experiments were carried out with an *R* strain of *D. pneumoniae* type II, obtained from the mucous form of *D. pneumoniae* type II in our laboratory by Griffith's method[8]. The crude extracts of deoxyribonucleic acid were obtained from young 4–6 hr. plate cultures of a strain of *D. pneumoniae* type III, by McCarty and Avery's method[9], using five- or six-fold deproteinization, but without specially removing the polysaccharides and ribonucleic acid. Ultra-violet absorption curves showed maxima in the region of 2580 A. and minima in the region of 2300 A.

Using as transformation method the experimental procedure of Avery *et al.*[3] it was found that the presence of salts with monovalent cations (dipotassium hydrogen phosphate, disodium hydrogen phosphate, potassium chloride, sodium chloride and to a lesser degree ammonium chloride and ammonium sulphate) in the classic neopeptone anti-*R* serum (10 per cent) medium[3], in concentrations of about 5 × 10^{-2} *M* to 10^{-1} *M* in the case of phosphates, and of about 10^{-1} *M* to 3 × 10^{-1} *M* in the case of chlorides, helped in the complete elimination of chance results in transformation of the *R* strain into the mucous form of

Results in three control series, in which the results were read off after 16, 20 and 48 hr. growth in the liquid medium by subculturing at the indicated time on to glucose blood agar plates twice from each test-tube. The macroscopic identification was confirmed by agglutination with the homologous immune serum. 0, No transformation found. +, Transformation positive.

D. pneumoniae type III. Neither the height of the agglutinating titre nor the sodium or potassium content of the anti-*R* sera used had any effect in the results given in Table 1. Transformation was not promoted by calcium chloride. In the presence of lithium and magnesium salts (probably activating deoxyribonuclease) and of cobalt, the medium was sterile.

It was verified experimentally that neither the phosphate buffer nor the quality of the anions was important, and the active part in successful transformation was played by the monovalent cations. Table 1, in which the control, that is, the plain neopeptone broth, shows negative results, gives the results of experiments with a 2- and a 4½-hour inoculum of the *R* strain, containing 220 and 1,330 cells respectively per ml. of the medium. Transformation of the *R* strain to the mucous form of pneumococcus type III commences, under the given conditions, at a concentration of 3×10^{-2} *M* for disodium hydrogen phosphate and 5×10^{-2} *M* for dipotassium hydrogen phosphate. In the presence of potassium chloride and sodium chloride, transformation commences at a concentration of about $1 \cdot 5 \times 10^{-1}$ *M*.

If transformation is observed throughout growth of the culture in the transformation system, the cells of an *R* culture can be successfully transformed in the presence of the above salts, from the commencement of the growth-cycle to the stationary phase. A young *R* culture requires a somewhat higher concentration of salts than an older culture to give uniform transformation results (Table 1).

It is possible that the part played by the above ions is related to the permeability of the cell membrane to the large deoxyribonucleic molecule, although they may act on the deoxyribonucleic acid molecule itself. The cell appears to become more permeable with age, when the outer membrane loses its vitality in the transition from Gram-positivity to Gram-lability, at the end of the logarithmic phase of the growth-cycle and at the commencement of the stationary phase. Gram-labile cells from the primary culture are also found in a newly inoculated medium at the onset of growth. This would provide an explanation of the finding[1] that transformation can be detected better in cells which have been growing from zero to two hours than later, during the active phase of the growth-cycle. At the end of the logarithmic phase the cells form large Gram-labile groupings. These are probably the same groups of susceptible cells described by Hotchkiss[2] which successively develop and disappear as the culture grows, remain capable of transformation for about 15 min. and then lose this property.

Applications of Erythrocyte Stromata Powder

BLOOD displaying positive serological reaction for syphilis and erythrocytes of blood stored for more than 21 days are usually discarded in blood banks. The erythrocytes of such blood samples were utilized for the preparation of erythrocyte powder. They were washed with saline and hæmolysed with distilled water. The stromata were then washed three times with distilled water cooled to 6° C. Thereafter, the stromata sediment was lyophilized and pulverized in a mortar. The drying could also be carried out at 37° C., the stromata being spread in a thin layer; but the lyophilized preparation was more active. About 1,500 mgm. of fine, pink powder was obtained from 200 ml. of packed red cells. The powder could be stored at 4° C. for at least two months without any appreciable loss of activity. Before use, the requisite amount of the powder was weighed out and washed twice with saline, care being taken to prepare a suspension free from lumps. In this way the powder was cleared of almost all remaining hæmoglobin.

Absorption of antibodies. The erythrocyte powder was successfully used for the absorption of anti-A and anti-B antibodies from test sera of human origin (anti-Rh, anti-Duffy, anti-Kell, etc.). 10–20 mgm. of powder were used for the absorption of 1 ml. of serum. First, a small amount of serum was added to the washed powder sediment, and a diffuse suspension was prepared by vigorous stirring with a glass rod; then the remaining volume of serum was added. The tubes were kept for 2–3 hr. at room temperature, being frequently shaken. Thereafter, the tubes were centrifuged and the serum withdrawn. The absorption performed in this way was almost always complete, and it had to be repeated only in exceptional cases. The absorption of anti-A and/or anti-B antibodies from anti-D serum could be performed not only with Rh-negative but also with Rh-positive erythrocyte powder heated after washing (as a moist sediment) for 10 min. at 56° C.

Absorption of anti-human hetero-agglutinins from rabbit anti-globulin serum was performed by the same technique, the powder of A erythrocytes being used preferably.

For the absorption of anti-D antibodies, 50 mgm. of Rh_0-positive powder per 1 ml. of serum was used. The absorption required 2 hr. at 37° C. Repeated absorptions were frequently required for complete exhaustion of antibodies.

Preparation of 'pure' antibodies. The elution of blood-group antibodies from the red cells has been practised since 1925 [1], but the methods used did not yield 'pure' antibodies in a high titre or in a solution free of ballast proteins. Some progress was made by the application of stromata[2,3].

50–200 mgm. of powder was sensitized with 10–100 ml. of serum. Sensitization with anti-A and anti-B antibodies occurred over a period of 2 hr. at room temperature, and, with anti-D, 2 hr. at 37° C. The sensitized powder was washed three times with saline and suspended in saline or AB serum. About one drop of saline or serum was added per 4 mgm. of powder. The tubes were shaken for 5–7 min. in a water-bath at 56° C., and centrifuged in a 500-ml. flask filled with water warmed to 56° C. The eluate was then withdrawn. The saline eluates were water-clear and contained only about 10 mgm. per cent proteins. The titre of the anti-A and anti-B antibody preparations was up to 1,000.

The anti-D antibody eluate obtained in AB serum had all the properties of an incomplete anti-D serum, titres up to 1 : 2,000 being obtained in colloidal medium. In this way, an anti-D serum group O could be 'changed' into an anti-D serum group AB.

The anti-D antibody eluate obtained in saline did not agglutinate Rh_0-positive cells, but it sensitized Rh_0-positive red cells up to a dilution of 1 : 100 for the action of Coombs serum. Washing the sensitized cells could be omitted without any influence on the reaction. The indirect Coombs test could also be performed by adding saline suspension of Rh_0-positive cells to the mixture of Coombs serum with saline eluate of anti-D. This phenomenon can be explained by the lack of normal globulins in the saline eluate. This observation may possibly be of practical importance for the simplification of the indirect Coombs technique.

Complement fixation test. All test components were added in 0·25-ml. volumes; inactivated serum at 1 : 5 dilution, erythrocyte powder in suspension containing 1–5 mgm./ml. Fixation and incubation were performed at 37° C. Out of forty-three normal sera tested, only five gave positive reactions due to anti-A and/or anti-B antibodies. Three sera from women belonging to group O, who gave birth to infants with hæmolytic anæmia due to ABO incompatibility, were also tested. Two of these sera, with high titre of anti-A and anti-B respectively, gave a strongly positive reaction with A and B erythrocyte powder respectively. The third serum, with a high titre of anti-A, gave only a doubtful reaction.

Immunization of rabbits. A suspension containing 20 mgm. of washed powder injected daily intravenously into rabbits produced no morbid symptoms. Very large amounts of powder could be given subcutaneously or intramuscularly without doing any harm. The application of this method for MN immunization is under investigation.

Production of High-Titre Diphtheria Toxin in Baffled Shake Flasks

SUCCESSFUL production of high-titre diphtheria toxin has already been described[1], involving aluminium tanks containing 10 or 50 l. of medium. The inoculated medium was stirred at 1,400 r.p.m. so that a vortex was produced, and under these conditions high-titre toxin was obtained in 48 hr. The inocula for the tanks were produced in shake flasks[2] which gave relatively poor results after 48 hr. shaking, and which could not in any way be compared with tanks. Thus no simple method existed which would give high-titre toxin in 48 hr. and which could be used on a scale small enough to allow the easy handling of large numbers of cultures in the laboratory. It was felt that some improvement might be expected if the aeration of the shake flasks was improved, and this led to the use of baffled shake flasks[3]. In the present work 1-l. Erlenmeyer flasks were used, into which single glass baffles (approximate dimensions, 50 mm. high, 25 mm. wide and 1 mm. thick) were fused. On a rotary shaker (140 r.p.m., ½ in. radius) these gave an oxygen uptake at the start of the shaking period of 120 ml. oxygen/100 ml./hr. as measured by the sulphite oxidation technique[4]. This compared with 30–40 ml. oxygen/100 ml./hr. for an unbaffled flask under the same conditions, and the difference was due entirely to the surface of the medium being continuously broken up on the baffle. When no baffle was present the surface of the medium as it swirled around in the flask remained unbroken and no air bubbles were incorporated into the liquid.

For studies on toxin production, the flasks, plugged with cotton wool, and containing 100 ml. medium (either a tryptic digest medium based on that described by Linggood and Fenton[2] or a papain digest medium based on that of Ramon *et al.*[5]) were inoculated with 1 ml. of a 48-hr. culture of a Park-Williams No. 8 strain of *Corynebacterium diphtheriae* previously grown in an unbaffled shake flask. The flasks were placed on the shaker, which was in an incubator room at 35–36° C., and the toxin production was estimated 48 hr. later. A comparison of results from baffled and unbaffled flasks and tank cultures is given in Table 1.

Table 1. *Lf*/ML. VALUES OF FILTRATES OF *C. diphtheriae* GROWN FOR 48 HR. IN SUBMERGED CULTURE

Medium		Unbaffled flasks (average of 3 × 100 ml. cultures)	Baffled flasks (average of 3 × 100 ml. cultures)	Aluminium tanks (average of 4 × 60 l. tanks and 3 × 10 l. tanks)
Papain digest	*BP* 489	100	260	195
	BP 490	30	130	250
	BP 491	—	260	265
	BP 494	80	160	165
	BP 508	180	190	215
	BP 530	—	250	285
	BP 535	95	165	305
Tryptic digest	*P* 1,457	—	235	210
	P 1,458	—	240	195

A big improvement is seen in the toxin titres produced on most batches of media when baffled flasks are compared with unbaffled ones, and it is clear that the new method is often comparable with tank culture. With some batches of media (for example, *BP* 508), however, no advantage of baffled over unbaffled flasks was found, and further, when baffled flasks are compared with tanks, some media give much better results in the tanks (*BP* 535) and some much worse (*BP* 489). Thus the conditions under which toxin is produced in the two systems do not seem to be identical and conclusions drawn from the results produced in one method must be applied with caution to the other. A possible explanation of the differences lies in the different methods used for aerating the cultures. The oxygen uptake of the tank system is relatively low, being about 40 ml. oxygen/100 ml./hr., but since air is flowing continuously over the vortex this value should remain fairly constant. With baffled flasks the initial uptake of oxygen is high, but as the oxygen in the flask is used up it is replaced by air. Thus the oxygen available and the rate of uptake of oxygen diminish, and so the growing organism may be subjected to quite different sets of conditions in the two methods. This work suggests some relation between respiration and production of toxin in the organism, the exact nature of which is

Table 2. EFFECT OF DETERGENTS ON TOXIN TITRES PRODUCED IN BAFFLED SHAKE FLASKS

Medium	Detergent added	*Lf*/ml. (average of 3 × 100 ml. cultures)
BP 505	None	105
	0·1 per cent sodium stearate	265
BP 508	None	190
	0·05 per cent sodium stearate	220
	0·01 per cent 'Calsolene'	250
BP 512	None	195
	0·02 per cent 'Tween 80'	250

obscure, and it may be that optimum conditions vary for each batch of medium.

To illustrate the difference between flasks and tanks, the effect of detergents on production of toxin in baffled shake flasks is shown in Table 2. As can be seen, the results were sometimes quite dramatic, increases of 50–150 *Lf*/ml. being achieved. In view of this, detergents were added to tank cultures, but in that case they were without effect. The reason for this lack of conformity is not clear. It is known that stirring at 1,400 r.p.m. produces very much more foam in the medium than is ever produced in baffled flasks, and it seems possible that the detergent acts by forming a layer of foam in the baffled flask, thus slightly reducing the uptake of oxygen. This would imply that it is possible to over-aerate cultures of *C. diphtheriae* when high-titre toxin is being aimed at, and further work along this line is in progress.

I wish to thank Dr. C. G. Pope for many helpful discussions and Mr. C. Van-Toller for his able technical assistance.

Dependence of Bone Marrow Cells on the Liver for Purine Supply

IT is well known that higher organisms can utilize the carbon atom of formate molecules for the synthesis of purines, as indeed can liver tissue *in vitro*. However, in rabbit and human bone marrows and in Ehrlich ascites cells of the mouse, formate-^{14}C was found to be utilized very inefficiently for *de novo* synthesis of purines *in vitro*, but very efficiently for labelling thymine in deoxyribonucleic acid[1–3]. As liver extracts restore the ability of these cells to synthesize purines *in vitro*[4], it was suggested that, *in vivo*, the capacity of bone marrow cells for synthesis of purines may be so limited that they depend on the liver for the supply of purines. This inference was tested experimentally by measuring the amount of formate-^{14}C incorporated into the deoxyribonucleic acid bases of bone marrow cells in control and hepatectomized rabbits.

Rabbits weighing 1·5–2·0 kgm. were used. They were bled on each of the two days before the experiment to ensure an actively regenerating marrow. Rabbit 1 was not anæsthetized, to serve as a control for the effects of anæsthesia (chloralose, 80 mgm./kgm.) in the others. In rabbits 4 and 5, as much of the liver as possible was removed (about 95 per cent). This procedure introduced two other factors which may have complicated the interpretation of the results : trauma and cessation of blood flow through the intestine. To test whether these conditions were influencing the results, further experiments were necessary. Both kidneys were removed from rabbit 3 as a control for trauma, and the intestinal tract was removed in rabbit 6. As this latter operation cut off a large proportion of the blood supply to the liver, it was repeated in rabbit 7, but with restoration of the portal blood flow by anastomosis of the inferior vena cava to the stump of the portal vein.

Five to ten minutes after the operations, sodium formate-^{14}C (500 μc./kgm., specific activity, 4 mc./m.mole) was given intravenously. The rabbits were killed by exsanguination 90 min. later and the femoral and tibial bone marrow was removed. The deoxyribonucleic acid bases in the bone marrow were isolated, and the specific radioactivity measured as described before[3]. The results are shown in Table 1.

There was little difference between the ratios of specific activity of thymine/adenine in the non-anæsthetized control, anæsthetized and nephrectomized rabbits. The mean ratio was 1·05, indicating a similar degree of incorporation of formate-^{14}C into both the purines and the thymine of the deoxyribonucleic acid in bone marrow cells *in vivo*. More labelled adenine was found in the bone marrow from the unanæsthetized rabbit, giving a ratio for the specific activity of thymine/adenine of 0·5, but because of the expenses involved, further experiments to test the significance of this difference were omitted.

In the hepatectomized rabbits, the incorporation of formate-^{14}C into the adenine of bone marrow cells was substantially depressed, thus raising the thymine/adenine ratio to 27. A similar thymine/adenine ratio was found in the rabbit where the intestine was removed, with arrest of the portal circulation. In the rabbit in which portal blood flow was restored after removal of the intestines, the thymine/adenine ratio was 3·17, indicating that formate-^{14}C was efficiently utilized in the formation of bone marrow adenine. This was in spite of the fact that intraportal injection of ink stained only about 50 per cent of the liver at the end of the experiment. In

Table 1. SPECIFIC ACTIVITIES OF THE THYMINE AND ADENINE OF DEOXYRIBONUCLEIC ACID FROM RABBIT BONE MARROW 1½ HR. AFTER AN INTRAVENOUS ADMINISTRATION OF 500 μC. FORMATE-^{14}C PER KGM. BODY-WEIGHT (COUNTS PER MIN./μM BASE)

	Rabbit 1, control, no anæsthetic	Rabbit 2, control, anæsthetic	Rabbit 3, control, nephrectomy	Rabbit 4, hepatectomy	Rabbit 5, hepatectomy	Rabbit 6, portal occl.	Rabbit 7, caval-portal anastomosis
Thymine	450	600	570	138	40	347	589
Adenine	900	380	543	5	1·5	17	186
Ratio (*T*/*A*)	0·5	1·6	1·05	28	27	20	3·17

one animal (rabbit 5) the blood pressure fell to 35 mm. mercury soon after hepatectomy and, as might be expected, the synthesis of both purines and thymine was depressed. Nevertheless, the thymine adenine ratio still indicated the importance of the liver for the synthesis of purines.

These experiments show that the *de novo* synthesis of purines in bone marrow cells is greatly reduced by hepatectomy. It is unaffected by nephrectomy or by removal of the gastro-intestinal tract, as long as the portal blood flow is maintained. Three interpretations of these results are suggested: (1) In animals, the liver provides an enzyme with which the bone marrow cells can synthesize purines. (2) The liver provides an advanced precursor which the bone marrow cells can transform into purines. (3) The liver supplies preformed purines which are taken up by bone marrow cells.

If the liver provides an enzyme, it must have a very short life, for in our experiments even 5–10 min. after hepatectomy the bone marrow cells cannot utilize formate-^{14}C efficiently for synthesis of purines.

If the liver supplies an advanced precursor to the bone marrow, then bone marrow cells *in vitro* should be able to utilize 5-amino-4-imidazole carboxamide or its riboside (one of the last steps in the purine pathway). It has recently been shown[5] that these substances are utilized very inefficiently for synthesis of purines compared with the uptake of adenine-^{14}C into purines or of formate-^{14}C into thymine.

This leaves the third possibility, which is further supported by the observations that although bone marrow cells *in vitro* have a limited capacity for purine synthesis, they can utilize preformed adenine very efficiently[6]. We can conclude, therefore, that in the mammalian organism, the liver is the main source of purines for the bone marrow cells, and possibly for the cells of most peripheral tissues.

Elimination of Macrophage Cells of the Reticulo-Endothelial System by Way of the Bronchial Tree

IT has been demonstrated by Nicol[1] that vitally stained macrophages appear cyclically in the uterine endometrium and that they are greater in number in the follicular phase of the œstrous cycle and their number and activity may be increased experimentally by œstrogens. The dye-bearing macrophages were not observed within the uterine blood vessels although some were seen to lie close to them. The appearances throughout the uterus and vagina provided convincing evidence that the dye-bearing macrophages are similar to many of the rounded cells, with dense nuclei and no dye, frequently seen within the capillaries and passing through the blood vessel walls in the circular muscle zone. From this it was inferred that the blood is the chief source of these macrophages, although some of them may be derived from the connective tissue cells of the endometrium.

It was later shown by Nicol and his colleagues[2] that œstrogens have a strong stimulating influence on the reticulo-endothelial system generally and that this results in the appearance of large numbers of macrophages in the spleen and liver and the mobilization of these cells into the circulation. In the spleen of control animals a relatively small number of vitally stained cells was normally present in the sinuses and in the reticulum, and in the liver only a few dye-bearing Kupffer cells were seen. After œstrogenic treatment, however, the number of dye-bearing cells became considerably increased in both liver and spleen and many of these were liberated and could be seen free in the splenic sinuses, splenic vein and intralobular veins of the liver, but they were not seen in the splenic artery. The present research was designed to study the fate of the hepatic and splenic macrophages which become free and enter the bloodstream.

For this investigation 36 male white mice (T.O. Swiss strain) of 20–30 gm. body-weight were used. Each animal received one subcutaneous injection of 0·5 mgm. of œstradiol benzoate once daily for 6 days and then one injection of 4 mgm. of carbon of particle size 250 A. into the dorsal vein of the penis on the eighth day. The animals were divided into six groups and blood samples were taken under anæsthesia at either 2 min., 2 hr., 1, 2, 3 or 4 days after the carbon injection from each of the following sites—splenic vein, portal vein; hepatic vein, inferior vena cava, right heart; left heart, retro-orbital plexus, saphenous vein. The animals were then killed and smears were taken from the lungs and bronchi, and the trachea was tied at two points and an isotonic solution of saline used to wash out the contents of the lumen for microscopical examination. In addition, specimens of the liver, spleen and lungs were fixed in Heidenhain's 'Susa' fluid and sections were cut 10μ thick and stained with dilute eosin or carbol fuchsin.

The results were as follows: carbon-containing macrophages were found in the splenic sinuses, splenic vein, portal vein, liver sinusoids, intralobular veins, hepatic vein, inferior vena cava and right heart blood; but were not seen in the left heart blood, retro-orbital plexus and saphenous vein.

Two minutes after the injection a considerable amount of carbon was seen in the macrophages of the spleen and liver and a heavy concentration in the lumen of the capillaries of the lungs. Two hours later the macrophages of the spleen and liver contained a great amount of carbon, but in marked contrast no carbon was seen in the lungs. Forty-eight hours later a small number of carbon-containing macrophages was seen in the alveolar walls of the lungs, and 4 days after the injection a moderate number could be seen free in the alveoli. Carbon-containing macrophages were also found in the smears from the lungs and bronchi and in the washings from the trachea; they were well differentiated in the bronchi and lower trachea but in the upper respiratory passages they were disintegrating.

It has previously been reported[3] that when a known amount of carbon is injected intravenously about 90 per cent of the carbon is removed from the blood by the Kupffer cells of the liver, 3 per cent by the phagocytes of the spleen and the remainder by those of the bone marrow, lymph nodes and connective tissue. In the present investigation our use of œstrogens to stimulate the reticulo-endothelial macrophages and of carbon as a marker has enabled us to identify, not only the liver and spleen as the important sites of active phagocytosis, but also the distribution of the hepatic and splenic phagocytes liberated into the circulation, and their elimination by the lungs.

Florey[4] states that the lung is particularly rich in phagocytes, whatever their origin, for there is a constant demand for their activity to keep the alveoli clear of dust particles and other material. He states that in some species cells have been described within the alveolar walls which are thought to be capable of becoming detached phagocytes, but probably many of the lung phagocytes develop from blood monocytes. He also points out that it has been suggested that they may be replenished by showers of cells produced by division of the Kupffer cells of the liver which enter the circulation and are caught up in the lung capillaries. The cells then pass into the alveolar spaces and are seen there as large round cells containing particles like carbon from the air or hæmosiderin from extravasated red blood cells, and many of them probably pass up the bronchial tree.

Our results show that the blood channels within the lungs are poor in phagocytes, but that under certain conditions there is a liberation of phagocytic cells from the liver and spleen which enter the circulation and pass to the lung capillaries; and that when they contain ingested material like carbon they do not travel through the lungs into the left heart and peripheral circulation but pass into the bronchial tree and up the trachea to be expectorated or swallowed. Our evidence therefore gives support to the concept that the lung macrophages may be augmented or derived from the liver and spleen. It may be that the heart failure cells and dust cells of the lungs are also of hepatic and splenic origin.

The results appear to be of clinical significance since they indicate one method by which disease may be disseminated.

Lack of 'Slow-Alpha' Proteins in some Guernsey Cattle

Out of about 2,500 cattle sera examined during the past two years by starch gel electrophoresis[1], two individuals were found which lacked a slow alpha (Sα) protein zone (Fig. 1). Both animals were Guernsey cattle, one a five-year-old cow and the other her twelve-month-old heifer calf. This suggests that the condition is inherited. The herd from which the cow originated was examined for the absence of Sα-proteins. The part of the pedigree which is relevant is shown in Fig. 2.

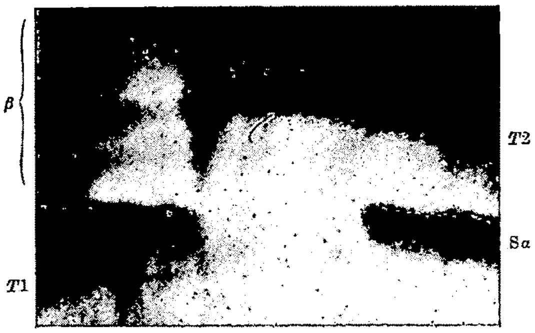

Fig. 1. Part of the anodic side of a starch-gel electropherogram carrying three cattle sera, the central one lacking Sα-proteins. β, β_2-globulins; *T*1 and *T*2, thread proteins

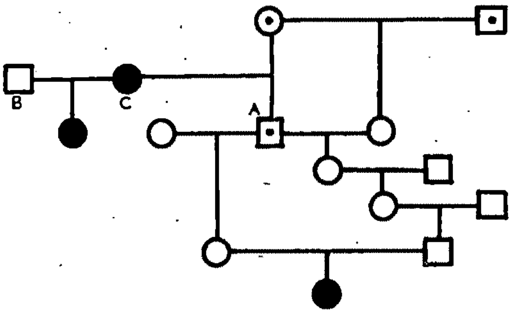

Fig. 2. Pedigree of part of a Guernsey herd in which some animals lack Sα-proteins. Solid circles denote affected females. Symbols with dots indicate animals which were not available

It seems likely that the Sα-protein (or proteins) is controlled by a pair of allelomorphic genes, $S\alpha^A$ and $S\alpha^O$. The genotypes $S\alpha^A/S\alpha^A$ and $S\alpha^A/S\alpha^O$ would then give phenotypes with Sα-proteins, while the genotype $S\alpha^O/S\alpha^O$ would lack them.

The relatively high frequency of $S\alpha^O$ in this herd seems to be due to a bull (unfortunately dead) which must have been homozygous for this allele. This particular bull (*A* in Fig. 2) was the result of a cross between two animals which had the same dam.

Insufficient information is available to assess the frequency of $S\alpha^O$. However, the bull *B* (Fig. 2), presumably $S\alpha^A/S\alpha^O$, is at present standing at a cattle breeding centre and is used extensively. No further examples of individuals lacking Sα-proteins were found among his progeny from fourteen matings picked at random from other herds.

The animals lacking Sα-proteins were in good health and did not show any signs of abnormalities. In fact, the five-year-old cow (*C*, Fig. 2) gave the best individual milk yield of cows in milk-recording Guernsey herds in Staffordshire for two successive years. Each of the bull *A*'s five daughters in the herd has shown a milk yield above average in each lactation.

The nature of the Sα-proteins in the cow is not known, but an analogous protein in humans has been shown recently by Poulik and Smithies[2] to be a glycoprotein of high molecular weight. A protein zone of this type has been found in all the mammalian sera so far examined, with the exception of the Guernsey cattle shown in Fig. 2 and two horse sera.

I wish to thank Mr. K. O'Sullivan, deputy regional veterinary officer of the Milk Marketing Board, for his generous co-operation.

Emergence of a Summer Species of Dragonfly

Two types of British dragonfly have been recognized, namely, spring and summer species. Spring species (for example, *Anax imperator* Leach, *Pyrrhosoma nymphula* (Sulzer)) have been defined as those having a diapause in the final larval instar and, in consequence, a closely synchronized emergence. In summer species (for example, *Aeshna cyanea* (Müller), *Lestes sponsa* (Hansemann)) diapause is by definition absent from the final instar, although sometimes developed in another stage in the life-history[1]. The lack of a final instar diapause in summer species made it seem likely that emergence in this ecological group would be less closely synchronized than in spring species, and that in some cases it might inherit from the larval population a time-frequency distribution approaching normality[2]. Although emergence of *L. sponsa* has been found to be temporally dispersed[3], when compared with that of *P. nymphula*[2], its exact temporal distribution and duration have hitherto remained unknown. Recently, however, the emergence pattern of another summer species, *A. cyanea*, has been determined directly by means of exuvia counts made in Nature, and the results provide a striking confirmation of expectation.

In Fig. 1 the emergence curve of *A. cyanea* is compared with that of *A. imperator*, a spring species in the same family and of similar size. The two curves differ significantly in the degree of their synchronization, a point well demonstrated by comparing the times during which 50 per cent of the annual population emerged: this stage was reached by the third day of emergence in *A. imperator*, but not until the twenty-fifth day in *A. cyanea*. Total duration of emergence in the two species was, however, approximately the same, being 44 days and 49–55 days, respectively.

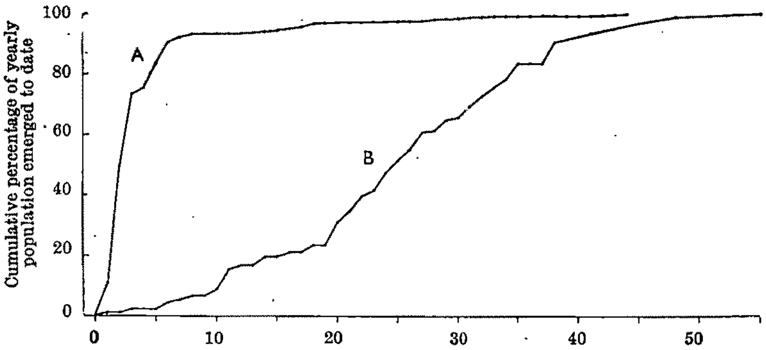

Fig. 1. Time-frequency distributions of adult emergences in (*A*) a spring species and (*B*) a summer species. *A*: *Anax imperator* in Berkshire during 1953; emergence began on May 25 and finished on July 7. *B*: *Aeshna cyanea* in Hampshire during 1957; emergence began on June 29 and finished between August 16 and 22

Such large differences in the temporal distribution of emergence will have important effects on other stages in the life-history. For example, early population pressure at the breeding site, and the resulting dispersal during the first few days of maturity, will probably be far more pronounced in spring species than in summer species. Also, the ecological demand for reproductive longevity will supposedly be greater in summer species, in which adult populations are heterogeneous with respect to the age of their members. In this connexion it is interesting to note that, in a Dorsetshire pond, Moore[4] found the flying season of *A. cyanea* to be very much longer than that of *A. imperator*.

Feeding Habits of Emperor Penguins

The feeding habits of emperor penguins (*Aptenodytes forsteri* Gray) have been described by previous authors[1–5]. Most agree that the birds have access to the sea through tide cracks. During the winter of 1957 in Antarctica, I was able to observe this phase of the birds' activities and can now amplify previous comments.

The breeding cycle of the emperor penguin is peculiar in that it occurs in the depth of the antarctic winter. After the laying of the single egg (in May in most rookeries) the female bird leaves the rookery for approximately nine weeks while the male bird incubates it. No trace of the females is seen until hatching commences, when they return in large numbers to the rookery to commence feeding the chicks while the males go to sea to end their long fast. The chicks grow rapidly, and the constantly increasing demand for food means that both parent birds travel to and fro from the feeding places, gorging themselves with fish and krill, then regurgitating food for the chicks.

Taylor rookery (67° 28′ S., 60° 53′ E.), fifty miles west of the Australian National Antarctic Research Expedition's base Mawson, is unique in that it is situated in an old glacial valley adjacent to the sea. All other known rookeries, with the exception of the one at Dion Islets, are located on sea ice. It is flanked by a glacier on its western side and is surrounded by a ring of high hills which afford much protection from wind. During the chick-feeding period here, the majority of birds do not travel more than two or three miles to feeding holes. Between the glacier and some nearby islands are a number of tide cracks, parts of which are kept open by glacier movement, Weddell seals, and feeding emperor penguins which congregate in large numbers near these holes. An interesting fact is that the birds do not feed for very long at these holes. Presumably this is because fish and krill in the area rapidly diminish against the onslaught of many hungry birds. When this occurs the hole is deserted and the birds move elsewhere.

At this time of the year, a few birds are seen to travel seawards past the thickly populated feeding grounds, and are probably going farther afield for food, although I did not follow these birds.

A new emperor penguin rookery was discovered by an Australian party in August 1957 at approximately 67° 25′ S., 64° 00′ E. It is situated on sea ice held in by grounded bergs. At this time its population was approximately 12,000 adults and 8,500 chicks. A large feeding hole was found at the same time six miles south of the rookery at the base of a tilted iceberg. There were nearly 100 birds present, with many large groups of birds going to and from it.

The complete absence of female birds near the antarctic coast during the incubating season means that they must travel far out to sea, possibly to the pack ice fifty or one hundred miles away. However, their mode of travel is almost certainly not walking. In May several of these females were seen to enter the water through seal holes close to the Fold Island rookery (67° 20′ S., 59° 23′ E.), 90 miles west of Mawson, and appear again at more distant holes. Swimming from hole to hole beneath the sea ice would provide them with a much more rapid method of travel than walking, and it would be possible for them to cover large distances in a relatively short period.

An Outbreak of Subcutaneous Tumours in Rhesus Monkeys

SUBCUTANEOUS tumours have developed in a colony of Indian rhesus monkeys (*Macaca mulatta*) at the laboratories of the West African Council for Medical Research, Lagos, Nigeria. We are using the word 'tumour' in a wide sense without any implication that the growths described are true neoplasms.

The colony in which the outbreak occurred consisted of approximately thirty-five animals housed in a row of four adjacent pens, with indoor and outdoor compartments; two further pens, situated at one end of these four pens and adjacent to them, contained various West African monkeys. A row of six smaller pens was situated 100 yards from the main rhesus pens and at the time of the commencement of the outbreak housed other assorted West African monkeys. Contact between monkeys in adjacent pens frequently occurred by the extension of a limb of one animal through to the next cage. The rhesus monkeys in the affected colony varied in age from new-born to approximately six years. The majority of adults had, at one time or another, been used for virus studies and had been returned to the pens after recovery from infection.

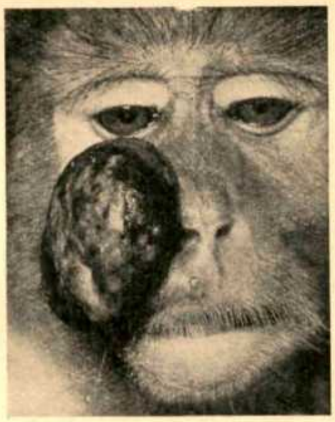

Fig. 1. Adult female rhesus monkey (case 2) with growth of three and a half weeks duration

No tumour had been observed in any species of monkey prior to June 15, 1957. On this date an adult male rhesus monkey, housed in one of the two centre pens, was seen to have a tumour, approximately 1 cm. in diameter, on the right eyebrow. During the following week the growth rapidly increased in size and an adult female situated in the other of the two centre pens was found to possess a similar growth on the nose (Fig. 1). During the ensuing weeks the condition spread rapidly, and by the end of the year had affected approximately twenty animals. In the early stages an unsuccessful attempt was made to limit the outbreak by separating tumour-bearing animals into individual cages; later, affected rhesus monkeys were placed in three of the six smaller pens normally housing West African monkeys. During October 1957, one young dog-faced baboon (*Papio papio*) situated in one of the three remaining small pens was found to have developed a tumour on the nose.

During the course of the outbreak, animals of all ages became affected by the condition. Tumours occurred most frequently on the lower portion of the limbs or dorsal aspect of the feet and hands, otherwise on the face or ears, never on the trunk. Affected animals did not appear sick or emaciated and seemed to be little inconvenienced unless suppuration of the tumours took place. During the early stages of the outbreak the condition appeared to be relatively mild, only single tumours occurring on affected monkeys; but as the outbreak assumed greater proportions an apparent increase in severity occurred, multiple tumours arising along the course of the lymphatic vessels draining a tumour-bearing area. Unless destroyed, affected animals recovered spontaneously, the growth sloughing away and the area healing by granulation. No attempt was made to treat the condition other than by local excision of tumours and the combating of secondary infection.

The tumours arose in the subcutaneous tissue, and in the earlier stages were seen as small, slightly reddened papules. Once initiated, growth ensued with great rapidity, tumours fungating through the skin and attaining a diameter of 2–4 cm. in as many weeks. At biopsy and post-mortem examinations the tumours were found to be adherent to the underlying structures and to be non-encapsulated. On section the tumours were light pink in colour and without visible structure. The regional lymph nodes

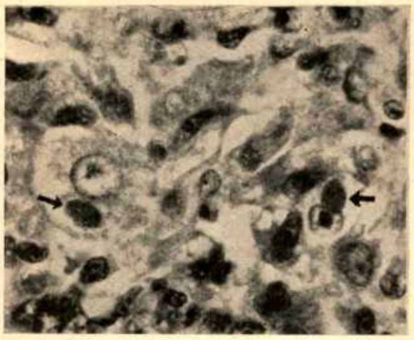

Fig. 2. Section of tumour showing cytoplasmic bodies (arrows)

were frequently enlarged but freely mobile. No metastases were found in any of the viscera in animals brought to autopsy.

Histological examinations showed that the bulk of the tumour was composed of pleomorphic cell types, the predominant cell (Fig. 2) being large with abundant cytoplasm. The cytoplasm of the majority of these cells contained one or more acidophilic, rounded or irregular bodies varying in size between 1 and 5μ and resembling virus-induced inclusions. In some cases there was a moderate degree of fibrous tissue reaction and an infiltration with inflammatory cells. No bacteria, fungi or protozoa were seen in tissue sections. In deeper layers of the growths tumour cells were frequently seen infiltrating between underlying muscle fibres. Enlarged regional lymph nodes were often seen to contain cells resembling those characteristic of the tumours.

The disease has been transmitted by subcutaneous inoculation of lightly centrifuged emulsions of tumour material to healthy rhesus monkeys and to two West African guenon monkeys (*Cercopithecus aethiops tantalus*). Attempts to transmit the condition to West African mangabeys (*Cercocebus torquatus torquatus*), to Patas monkeys (*Erythrocebus patas patas*) and to laboratory white mice have been unsuccessful.

Tumour material has been forwarded to Dr. C. H. Andrewes, National Institute for Medical Research, Mill Hill, London, for further investigation by his colleagues and himself; they have obtained evidence that the causative agent is a virus, as will be reported later.

Our thanks are due to Dr. F. N. Macnamara, director of the Virus Research Unit, for permission to publish this communication.

Epidermal Structures in a Rhinoceros (*Ceratotherium simum*)

Most accounts of rhinoceros skin detail its more obvious characteristics, namely, its rough, wrinkled and mammillated exterior, its well-keratinized epidermis and its thick, weighty and inelastic dermis. Concerning the structure of such skin and the possible presence of epidermal derivatives (other than horns) information is curiously wanting in authoritative zoological treatises[1]. It is frequently stated that body hairs, save those constituting the ear- and tail-fringes, are lacking in the Rhinocerotidae, though Beddard[2] recognized an unobtrusive and rather sparse hairy covering as a general familial character.

Neuville[3] observed hairs around the base of the horn in the three Asiatic species (*Rhinoceros unicornis*, *R. sondaicus*, *R.* (*Didermocerus*) *sumatrensis*), and Lydekker[4] considered *Didermocerus* a form specially prone to hairiness, the so-called species '*Rhinoceros lasiotis*' being based on nothing more than a particularly hirsute specimen. Bigalke *et al.*[5] described, in an infant *Ceratotherium simum*, a very sparse hairy covering, becoming less obvious with advancing age, and we have noted a discrete hair tuft upon the nuchal eminence of an immature animal of this species. Reliable records as to the hairiness of young specimens of *Rhinoceros unicornis*, *R. sondaicus* and *Diceros bicornis* appear to be lacking.

It is probable that in some rhinoceros species at least, as in the elephant, the neonatus manifests an extremely sparse hairy coat which disappears gradually either as the result of friction or the accumulation of subcutaneous fat.

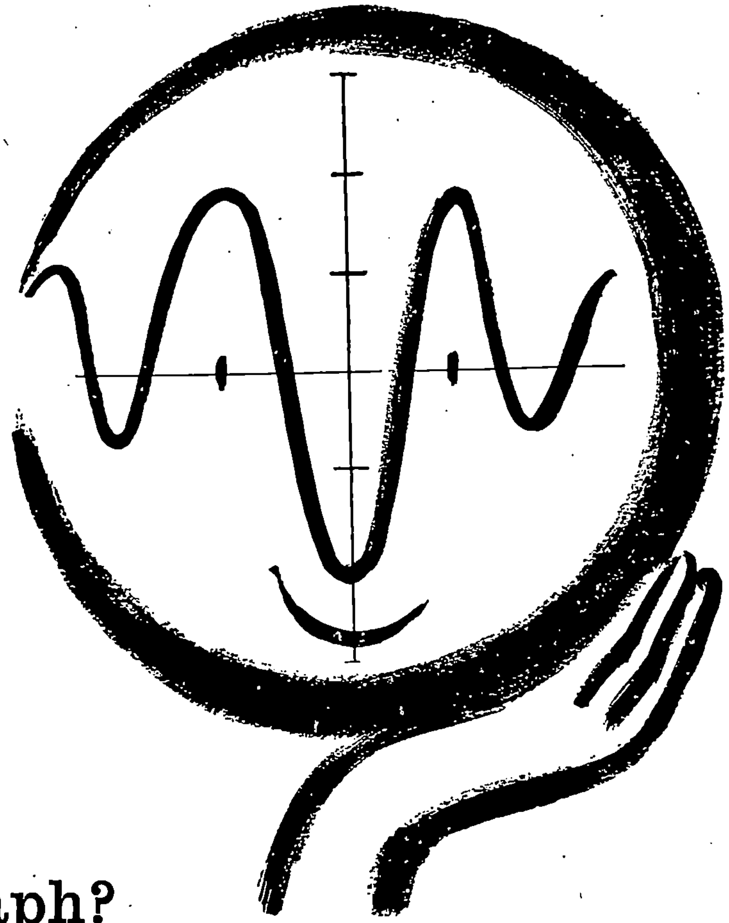
It is not surprising, therefore, that recent microscopical examination of the cervical and abdominal skin of an immature specimen of *Ceratotherium* should reveal the presence of hair follicles (provided with sebaceous glands) containing greater or lesser portions of well-formed hair shafts. Most unexpected, however, was the finding of large apocrine sweat glands, characterized by an abundance of relatively large, ectodermally developed myoepithelial cells, an anatomical arrangement clearly subserving the rapid and copious discharge of sweat.

The skin examined was freshly procured and well fixed in the field; after paraffin blocking it was sectioned with difficulty, the best sections being 15μ–20μ in thickness. These stained well with hæmatoxylin and eosin, and with Mallory's triple stain.

Study of these skin sections reveals (*a*) a heavily keratinized and pigmented epidermis, 1 mm. thick, showing the customary component layers save for a stratum lucidum, (*b*) an exceedingly thick (18–20 mm.) and dense dermis, composed exclusively of pure collagen fibres disposed in every direction to the skin surface, and (*c*) hair follicles, hairs, sebaceous glands and apocrine sweat glands. The entire skin appears remarkably vascular. The ordinary small type of sweat gland is not observable.

The obtrusively large apocrine sweat glands are not particularly numerous, although estimation of their incidence is precluded by the thickness of the sections. Each gland surrounds, in open basket fashion, the base of a hair follicle and appears to be supplied by an independent arteriole: its spiral duct is fairly capacious in its intra-dermal course, but narrows perceptibly in its intra-epidermal course. A striking feature of the glands and ducts is the association therewith of large and numerous ectodermally developed myoepithelial cells: these lie between the secretory cells and the basement membrane of the glands and are disposed helicoidally around the ducts.

These distinctive apocrine sweat glands seem to have escaped previous notice in *Ceratotherium* and it is not known whether they occur in other rhinoceros species. Histologically the skin of *Ceratotherium* is demonstrated to be of typically mammalian constitution and to lack none of the customary epidermal derivatives. It is specialized in respect of the degree of keratinization of its epidermis, the thickness and



Thinking about an oscillograph?

If you are experienced in the design of high quality instruments, our Technical Director would be glad to hear from you.

FOR USE IN ELECTRONICS? From the wide range of single and double-beam instruments, a model is available to suit the requirements of all sections of this expanding industry.

IN INDUSTRY? Diverse industries are finding solutions to their design and production difficulties with the aid of the Cathode Ray Oscillograph. Our Technical Advisory Service will be pleased to help you with your specific problem.

IN SPECIALISED FIELDS? Unusual types of oscillograph have been designed for specialised applications in the Hydraulic, Marine and Ultrasonic fields. We shall be pleased to consider specific development projects.

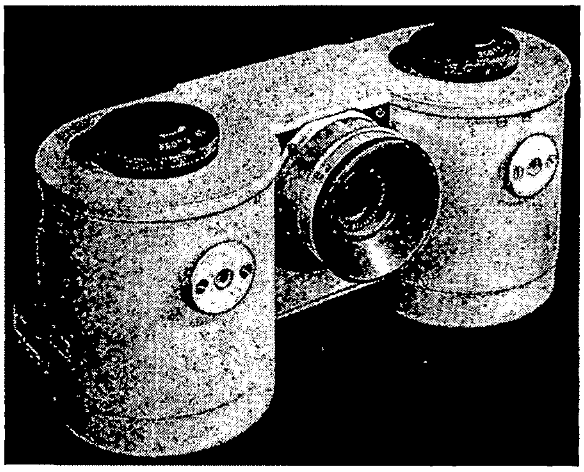
automation
in
photographic
recording



The Shackman Autocamera is a recording instrument designed to cover a wide field in industrial and scientific work where the automatic production of micro-films is required. It is a precision instrument suitable for all purposes where long periods of visual observation and manual recording are impracticable, such as Oscilloscope Recording, Process Timing, Photomicrography and Instrument Recording. It can be fully automatic in its operation, requiring only a short single electrical impulse to operate the shutter and transport the film. A full range of accessories is available including control units and intervalometers. The Autocamera is adaptable also for industrial photography, stereoscopy, document copying and many other special applications.

Lolium temulentum L., a Long-day Plant requiring only One Inductive Photocycle

COOPER[1] has recorded that *Lolium temulentum* is a long-day summer annual which shows no response to vernalization by low temperatures, and has no sharply defined critical photoperiod. My results, however, indicate that at least one strain of the species is a strict long-day plant, and that it can be induced to form normal inflorescences by exposure to only one long day.

The plants used were derived from the selfed progeny of a single Canadian plant, and were grown under controlled environmental conditions in the Earhart Laboratory, Pasadena. After seedling establishment in 8-hr. photoperiods, groups of plants were distributed to a series of photoperiod regimes at 17° C. under mixed incandescent and fluorescent illumination at an intensity of 1,200 ft.-candles throughout the photoperiod. The times of inflorescence initiation were determined by periodic dissection, and it may be seen from Table 1 that initiation was considerably delayed in photoperiods less than 12 hr. in length, and did not occur in 9-hr. photoperiods within 180 days. Initiation of inflorescences in this strain of *L. temulentum* thus appears to have an absolute requirement for long days.

Table 1. NUMBER OF DAYS REQUIRED FOR THE INITIATION OF INFLORESCENCES IN PLANTS OF *L. temulentum* GROWN AT 17° C. UNDER INCANDESCENT AND FLUORESCENT ILLUMINATION AT AN INTENSITY OF 1,200 FT.-CANDLES

Photoperiod length (hr.)	8	9	11	12	13	15	24
Days to double ridge appearance	—	>180	95	28	18	14	8

Groups of plants, which had been grown for five weeks in 8-hr. photoperiods, were exposed to a varying number of long days at 23–17° C. before being returned to short-day conditions. The rates of development of their inflorescences in short days at 23–17° C. subsequent to induction were determined by the dissection of five plants in each treatment group each week. All plants received 8 hr. of natural illumination daily, and during treatment were given photoperiod extensions at intensities of 12, 40 or 400 ft.-candles at plant height. Both continuous light and 16-hr. photoperiods were used for induction. Of the plants not exposed to long days, none showed any sign of inflorescence initiation within 140 days. Their apices did, however, increase in length throughout the period of the experiment, due to the accumulation of unexpanded leaf primordia. On the other hand, all the plants exposed to long-day conditions in all series, even those exposed to only one 16-hr. photoperiod of low intensity, either eared or displayed unambiguous inflorescence initiation on dissection. This strain of *L. temulentum* thus has a sensitivity to photoperiodic induction comparable to that of *Xanthium pensylvanicum* among short-day plants. It should be noted, however, that maximum photoperiodic sensitivity is not attained until the plants have been grown for about five weeks in short-day conditions at 23°–17° C. After only 14 days in that regime the plants need four days of continuous light for induction, while seedlings 21 and 26 days old require, respectively, three and two days of continuous light.

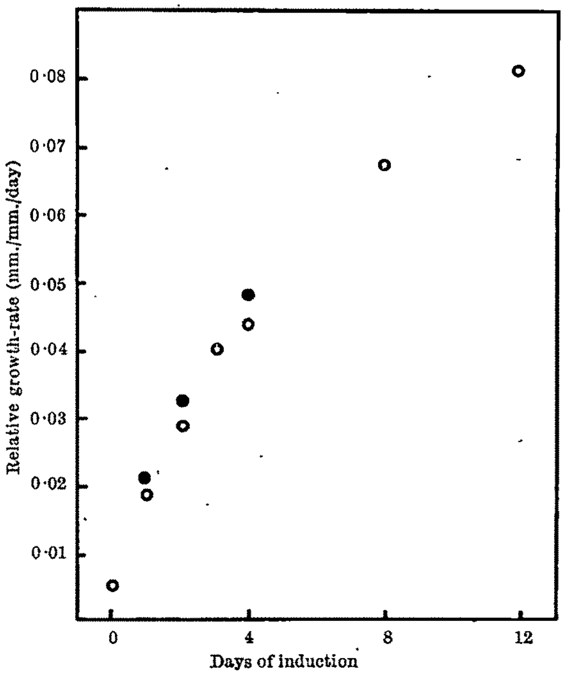

Fig. 1. The effect of the number of days of continuous light induction on the relative growth-rate of inflorescences of *L. temulentum* in 8-hr. photoperiods at 23–17° C.: with day-length extensions of 400 ft.-candles intensity, ○; with day-length extensions of 40 ft.-candles intensity, ●

In the controlled environmental conditions available for these experiments, the increase in apex length among induced plants was exponential with time, and it may be seen from Fig. 1 that the relative growth-rate of *L. temulentum* inflorescences, in 8-hr. photoperiods at 23–17° C. after initiation, was greatly affected by the number of long days to which the plants had been exposed. The rates were, in fact, approximately proportional to the logarithm of the number of inductive photocycles given. They were, moreover, highly reproducible, and provide a sensitive index for kinetic analyses of the inductive process.

Variation in the number of long days to which the plants were exposed had no effect on the number of spikelets formed in each inflorescence, nor were teratological features, such as sterility or vegetative proliferation, evident in any of the minimally induced inflorescences. This implies that there is a homeostatic canalization of inflorescence development (cf. ref. 2) whereby regulation of the rate of differentiation allows normal morphogenesis to occur in this species even under conditions of sub-optimal induction.

Chirality

The importance of particle parity, non-symmetric tensors in crystals, and other mirror-image properties, requires that a previous communication[1] be amplified, which suggested that, following Kelvin[2], Larmor and Eddington, the term 'chirality' be used for the property characterizing three-dimensional forms not superposable on their mirror images. Kelvin wrote[3] "I call any geometrical figure, or any group of points, *chiral*, and say it has *chirality*, if its image in a plane mirror, ideally realized, cannot be brought to coincide with itself". Unfortunately the definition in the Oxford English Dictionary—"*chiral*, the power of certain crystals and optically active substances of turning the plane of polarization of light to the right or left hand"—is not only less fundamental but misleads, since it is theoretically possible for crystals of four non-enantiomorphous classes (m, $mm2$, $\bar{4}$, $\bar{4}2m$), which are not chiral in Kelvin's sense, to display optical activity[4], though no example has yet been positively established.

The following generalization of Kelvin's definition is proposed (and has been offered for use in the next Supplement to the Oxford English Dictionary): 'three-dimensional forms (in the widest sense, including point arrangements, structures, fields, displacements, and other processes, periodic and relaxation) which possess non-superposable mirror images are called chiral'. This is a three-dimensional non-relativistic property; a chiral process is one the successive states of which are chiral. The necessary and sufficient condition for the presence of chirality is the absence of all three of the following symmetry elements: a plane of symmetry, a centre of symmetry, and any $4n$-fold inversion axis. The definition applies both to mathematical forms and to observed phenomena, and does not presuppose their representation in any particular manner (for example, in a linear, or any other co-ordinate system, etc.) provided the conceptions of mirror images and of superposition (by rotations) are applicable.

The terms 'chiral', 'chirality', 'chiroid' (for chiral object or process) are short, enjoy a distinguished tradition, and can be given an unambiguous and comprehensive definition. Alternative terms are either less general or vague: 'enantiomorphous', though in origin expressing the same idea, has acquired a narrower application through usage for the eleven chiral classes of point group symmetry and for crystals of these classes; 'asymmetrical' has an established meaning for carbon atoms and other chemical centres, but is otherwise ambiguous; 'non-symmetric' is best restricted to tensors; 'dissymmetric' has been used for chiral molecules and crystals, but not widely adopted; chemically 'isomeric' molecules may not be chiral; while 'anti-symmetrical' has a special meaning[5]—operations of anti-symmetry transform objects possessing two possible values of a given property from one value to the other.

Chiral forms are more varied and widespread than is sometimes realized. Some examples are: (mathematical) skew polygon, pair of skew lines, area with sense, various skew polyhedra, for example, an isosceles tetrahedron with scalene faces and Coxeter's "orthoscheme", helix, helical polygon, scalene spherical triangle, single overhand knot, eleven enantiomorphous classes of point group symmetry, ratio of two co-initial vectors, associations of a polar with an axial vector, quaternions, spinors, non-symmetric three-dimensional tensors, pseudo-scalar fields; (natural) most optically active molecules, crystals of the eleven enantiomorphous classes, many electromagnetic fields, screw displacements, body torques, torsions, relaxation processes of chirally deformed structures, amino-acid and protein structures, conical helices in plants and shells, many parts of animals (including the human hand); (man made) coat with buttoning for man or for woman, shoe, propellor, clock face. They merit a clear designation.

Note added in proof. 'Helicity' is a special case of chirality, involving helical properties with respect to an axis. Recent examples of chiral forms are the neutrino and the chiral operator of particle theory (Watanabe, *Phys. Rev.*, 106, 1306; 1957).

Motion of the Nodal Line of the Second Russian Earth Satellite (1957β) and Flattening of the Earth

Despite the fact that the observation of an artificial satellite can be carried out only on a small region of the Earth's surface, we can use these measurements for determining the geocentrical co-ordinates of the satellite, if we know the approximate value of its distance from the Earth's centre. The most suitable observations are those in the neighbourhood of the zenith. If we know the inclination of the orbit, we can then determine also the position of the orbital node.

In order to determine the motion of the orbital node, we used 33 visual observations, made between December 7, 1957, and March 21, 1958, at various places in Czechoslovakia. By adjustment of the positions of the node grouped about five normal positions, the following expression for the right ascension of the ascending node was derived:

$$\Omega = 256{\cdot}59^\circ \pm 0{\cdot}20^\circ - (2{\cdot}9007^\circ \pm 0{\cdot}0046^\circ)(t-t_0) - (0{\cdot}00234^\circ \pm 0{\cdot}00012^\circ)(t-t_0)^2$$

Epoch t_0 = January 22·0, 1958, U.T. Time t is expressed in days. The mean errors were computed from the deviations of the normal places. The daily motion of the node is then given by :

$$\frac{d\Omega}{dt} = -2{\cdot}9007^\circ \pm 0{\cdot}0046^\circ - (0{\cdot}00468^\circ \pm 0{\cdot}00024^\circ)(t-t_0)$$

It is well known that the theoretical value of this motion is given by the approximate equation :

$$\frac{d\Omega}{dt} = -\frac{3k(C-A)}{2ma^{7/2}}(1+2e^2)\cos i$$

where $C - A$ is the difference between the moments of inertia of the terrestrial spheroid, m the mass of the Earth and k the gravitational constant. The symbol a stands for the major semi-axis of the orbit, expressed in units of the equatorial radius of the Earth, e and i being the eccentricity and inclination of the orbit, respectively.

It is obvious that, by using this equation, we can derive from the observed motion of the node the quantity $K = \frac{C-A}{m}$. If, for the time $t = t_0$, we assume $a = 1{\cdot}1127 \pm 0{\cdot}0003$ and for e and i the values published by D. G. King-Hele[1], namely, $e = 0{\cdot}0731 \pm 0{\cdot}0005$, $i = 65{\cdot}29^\circ \pm 0{\cdot}03^\circ$, we then arrive at :

$$K = 0{\cdot}0010856 \pm 0{\cdot}0000024$$

The mean error was computed as the total effect of the errors of the basic data. The oblateness of the Earth, α, can be computed from the expression :

$$\alpha = \frac{3}{2}K + \frac{h}{2} + \frac{3}{4}(3K^2 + Kh - h^2)$$

where h is the ratio of the centrifugal force to the value of gravity at the equator.

The reciprocal value of the Earth's flattening is then :

$$\frac{1}{\alpha} = 297{\cdot}7 \pm 0{\cdot}3$$

If we use four more values for a and e determined[2] between February 10 and March 3, 1958, we arrive finally at the result :

$$K = \frac{C-A}{m} = 0{\cdot}0010883 \pm 0{\cdot}0000014$$

$$\frac{1}{\alpha} = 297{\cdot}4 \pm 0{\cdot}2$$

In these numerical results approximate account was taken of the second term of the disturbing function.

These preliminary results show that satellite observations of greater precision will give us the possibility of determining correctly the oblateness of the Earth.

Effect of Oxygen on the Electron Spin Resonance Spectrum of α,α′-Diphenyl-β-picrylhydrazyl

IT has been found that under certain conditions gaseous oxygen can have a marked effect on the electron spin resonance line of α,α′-diphenyl-β-picrylhydrazyl. Normally that substance crystallizes with one molecule of solvent per radical and does not exhibit this 'oxygen effect'. It is possible, however, to remove most of this solvent by heating the radical at 80° C. under high vacuum for several days. (There is no evidence that the radical is destroyed by this treatment.) The magnitude of the resonance line from a treated sample of α,α′-diphenyl-β-picrylhydrazyl depends strongly on the pressure of oxygen over the sample. The effect is similar to that observed in carbons, and appears to be a combination of the two extreme cases reported[1].

The electron spin resonance measurements were made at room temperature using a 3-cm. wave-length crystal-video spectroscope. The dependence of the width and apparent intensity of the resonance line on oxygen pressure has been studied (Fig. 1). In addition, the effect of altering the percentage of oxygen in an oxygen–nitrogen mixture has been observed. These latter results are identical with the former if the amount of oxygen present in the mixture is expressed in terms of its partial pressure. In both cases the effect of oxygen on the electron spin resonance line was completely reversible.

When the atmosphere surrounding the sample was changed from oxygen to nitrogen, or vice versa, a corresponding change in the resonance line occurred almost instantaneously. The fact that this change could be produced simply by displacing one gas by the other suggests that there is a dynamic interaction occurring between oxygen molecules and the unpaired electrons of the α,α′-diphenyl-β-picrylhydrazyl.

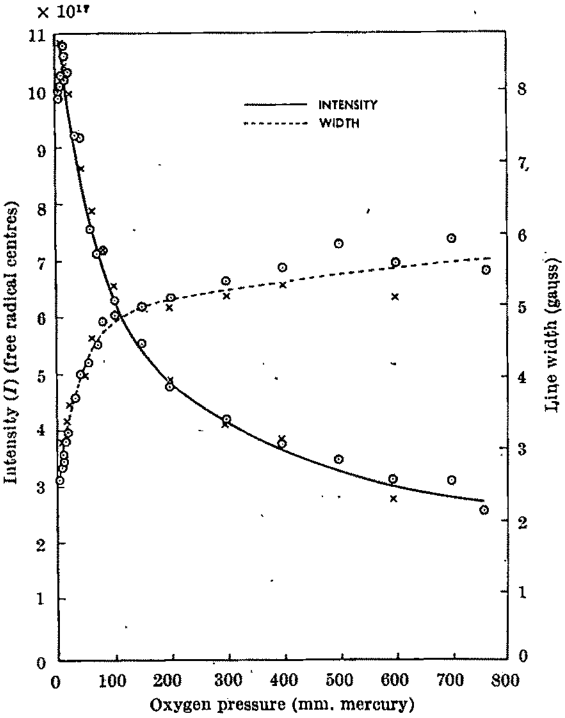

Fig. 1. Variation of intensity and width of resonance line with pressure of oxygen

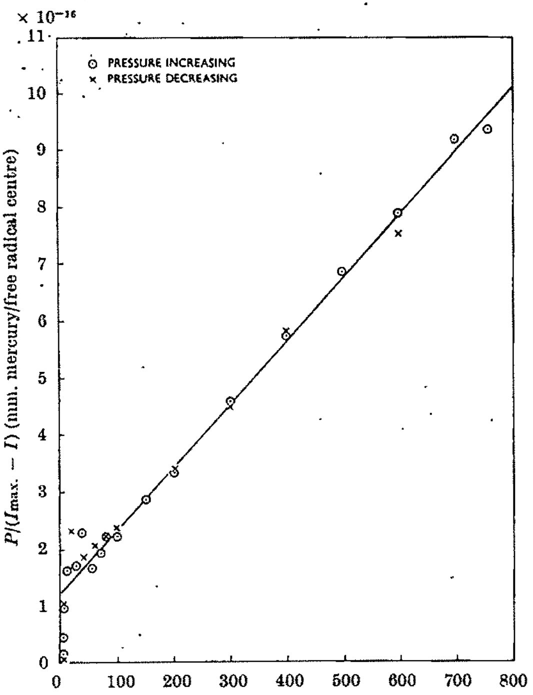

Fig. 2. Langmuir plot for adsorption of oxygen on α,α'-diphenyl-β-picrylhydrazyl

The results indicate that the interaction is physical rather than chemical in nature. It is unlikely that the decrease in the intensity of the resonance line is due to an actual decay of the free radical concentration, but that the line is broadened beyond detection. This broadening would appear to be similar to that postulated for carbon[2], where the interaction with the oxygen molecules decreases the spin-lattice relaxation time of the free radical spin system.

If the apparent decrease in the resonance line is assumed to be proportional to the volume of oxygen adsorbed, a reasonable plot of the Langmuir equation[3]:

$$p/v = 1/v_m b + p/v_m$$

can be obtained for pressures greater than 25 mm mercury. The value of the adsorption constant, b over this range is 7×10^{-6} dynes^{-1} cm.^{2}.

The electron spin resonance spectra from powdered samples of 1 : 3-dimethyl-1-(phenylimine oxide)-butylidene-3-N′-phenyl-N′-oxynitrogen[4] and 2 : 6-di-tert.-butyl-4-(3 : 5-di-tert.-butyl-4-oxocyclohexa-2 : 5-dienylidenemethyl) phenoxy[5] do not show any dependence on the oxygen pressure. However, dissolved oxygen causes a marked broadening of the spectrum from a dilute solution of the latter radical, and a slight broadening in the case of α,α'-diphenyl-β-picrylhydrazyl.

Entry of Water into Silica Glass

SOME specimens of silica glass absorb infra-red radiation of wave-length near 2·7μ. Garino-Canina[1] observed that the occurrence or absence of the band in his specimens depended on whether or not water vapour was present when the glass was made (by fusing quartz crystal). Following Harrison[2], he attributed the absorption to hydroxyl groups bound to some of the silicon ions of the glass.

We have demonstrated the ability of the absorbing centres to diffuse into the glass at temperatures low compared with the softening point. Values of diffusion coefficient and solubility have been obtained.

Specimens not showing the absorption band were heated at constant temperature and in a constant pressure of water vapour. The optical density of the band ($\log_{10}(I_0/I)$, where (I_0/I) is the ratio of radiation incident on the specimen to that transmitted) increased with the square root of time, suggesting that the number of absorbing centres present at any time was controlled by a diffusion process within the glass.

The distribution of the absorbing centres inside the laminar specimens of glass used was investigated by sectioning. The optical density was measured at each stage after successive layers of thickness about 10μ were removed from the surfaces of the specimen by grinding and re-polishing. Considerable penetration was found: for example, after 36 hr. at 1,160° C., absorption was detectable to a depth of 200 μ. The penetration profile appeared to be smooth and of the shape to be expected for diffusion in the existing boundary conditions.

The diffusion coefficient of the absorbing centres was determined as follows. One 'thick' and one 'thin' specimen were heated under the constant conditions of temperature and pressure of water vapour. The thickness of the 'thick' specimen was large compared with the diffusion distance, while that of the 'thin' one was small enough to allow saturation of the glass with the absorbing centres to be reached during the experiment. With the assumptions that the concentration of centres in the saturated thin specimen was uniform, and that this concentration was identical with that at the surface of the thick specimen (both assumptions being supported by experimental evidence from the sectioning work), the diffusion coefficient, D, was evaluated directly from the optical densities of the two specimens. Between 600° C. and 1,200° C., D could be represented by:

$$D = (1{\cdot}0 \pm 0{\cdot}2) \times 10^{-6} \exp\left(-\frac{18300 \pm 500}{RT}\right) \text{ cm.}^2 \text{ sec.}^{-1}$$

where R is the gas constant in cal./mole and T is the absolute temperature.

If the water reacts with the glass to form groups of the type (—Si—OH), their number may be estimated from the optical density provided the extinction coefficient is known. An estimate of the value of this coefficient was made by determining the extinction coefficient for the hydroxyl group in the unassociated molecule of triphenylsilanol (in which the —Si—OH group also occurs). The observed optical densities then led to values of solubility, under a pressure of 700 mm. mercury water vapour, ranging from 6×10^{-3} to 3×10^{-3} hydroxyl groups per 'silica molecule' between 600° and 1,200° C., respectively.

The dependence of the equilibrium concentration of absorbing centres on pressure of water vapour at constant temperature is at present under investigation.

Diffusion of Adsorbed Molecules

In a recent monograph[1], Carman dismisses the suggestion that the spreading pressure φ is the operative force in the diffusion of adsorbed molecules with the statement that the coefficient of resistance of such an equation varies more rapidly with concentration than does the diffusion coefficient of Fick's equation. In presenting his arguments for this view, Carman gives for diffusion under a spreading pressure the equation:

$$-\frac{W_s}{At} = B_\varphi \frac{\partial\varphi}{\partial x} \tag{1}$$

where W_s/At is the number of moles diffusing across unit area of adsorbent in time t under the influence of a gradient $\partial\varphi/\partial x$ of the spreading pressure. $1/B_\varphi$ is a two-dimensional resistance constant.

This equation does not represent the theory previously presented by me for the diffusion of adsorbed molecules. In the development of the equations for diffusion[2], I assumed the fundamental dynamical equation for the diffusion of an adsorbed gas to be:

$$\frac{\partial\varphi}{\partial x} + C_r u = 0 \tag{2}$$

where C_r is a coefficient of resistance and u is the resultant velocity of motion of the adsorbed film on the surface. From this equation,

$$u = -\frac{1}{C_r}\frac{\partial\varphi}{\partial x} \tag{3}$$

and

$$\frac{W_s}{At} = \frac{Nu}{N_A} = -\frac{N}{C_r N_A}\frac{\partial\varphi}{\partial x} \tag{4}$$

where N is the number of adsorbate molecules per unit volume of adsorbent and N_A is Avogadro's number. Equation 4 differs from equation 1 by the factor N and the presence of N destroys Carman's argument.

In these equations it is assumed that C_r, which is equal to the resistance force per unit volume at unit velocity, is a constant independent of N. An alternative assumption is that the resistive force per molecule is independent of N. This second assumption was investigated in a subsequent paper[3] and was found to be unsatisfactory. If C_m is the coefficient of resistance per adsorbed molecule:

$$C_r = C_m N \tag{5}$$

and

$$\frac{W_s}{At} = \frac{Nu}{N_A} = -\frac{1}{C_m N_A}\frac{\partial\varphi}{\partial x} \tag{6}$$

This equation is equivalent to equation 1 used by Carman. His argument, therefore, applies only to an equation which had already been tested and rejected.

The assumption in equation 2, that the resistive force per unit volume is independent of N, requires that the resistive force per molecule varies as $1/N$. Since it is natural to assume that resistive forces are proportional to the energy with which the molecules are bound to the surface, we should expect equation 2 to be applicable only to adsorptions where the differential heats are inversely proportional to the number of atoms adsorbed. That the equation can be applied to the diffusion of adsorbed gases is undoubtedly due to the fact that most heats of adsorption can be roughly represented by a hyperbolic curve. It follows from these arguments that, when this is not so, or when more precise representation is required, it will be necessary to use an expression for the resistive force that corresponds more closely to the measured heats of adsorption.

[3] Babbitt, J. D., *Can. J. Phys.*, **29**, 437 (1951).

In the brief treatment of Babbitt's theory in my book, equation 1 of the above communication was used, and it was pointed out that, with the experimental data available, B_φ, instead of being a constant, actually varied more rapidly with surface concentration than the surface diffusion coefficient which arises from Fick's equation. Babbitt now points out that, in the form of the theory which he has advocated, the correct expression is given by equation 4. According to this, the quantity which should be constant is not B_φ, but B_φ/N, where N is a measure of the surface concentration.

When this was applied to the data of Carman and Raal, it was found that B_φ/N in all cases varied much less than the surface diffusion coefficient and sometimes showed a remarkable constancy. Thus, for 'Freon 12' (CF_2Cl_2) on Linde silica, it showed little variation from a surface concentration of about one-half monolayer to about two and one-half monolayers, even though the surface diffusion coefficient passes through a maximum in this range. At higher concentrations it increases, but this could probably be ascribed to the action of capillary forces on capillary condensate. For sulphur dioxide on Linde silica, it is not quite so constant, but increases very little from one-half to two and one-half monolayers. Thereafter it rises fairly rapidly. In the case of 'Freon 12' and of carbon dioxide on 'Carbolac', it is only possible to state that, on the whole, the range of variation is less than for the surface diffusion coefficient; but it is not possible to distinguish any range where B_φ/N is even approximately constant.

As explained by Babbitt, a constant value of B_φ would result if the coefficient of resistance per adsorbed molecule were independent of surface concentration. This seems a natural assumption to make, but it was rejected by Babbitt because it did not fit the results of King for diffusion of water vapour through horn. He has preferred, therefore, to assume B_φ/N or C_r is a constant, and, on this basis, it can be seen that his theory deserves serious consideration, though it does not apply quantitatively to all systems.

Note added in proof. A rather remarkable further confirmation of Babbitt's equation has been given recently by Gilliland, Baddour and Russell[1] for flow in porous glass plugs.

Rubidium Depletion in Feldspars

The close geochemical coherence of potassium and rubidium has been emphasized in a number of papers by Ahrens and co-workers[1-4].

This coherence is shown in Fig. 1. The dashed lines on the diagram indicate the limits of scatter of Ahrens's original data, and most subsequent analyses fall within these limits, which are taken to indicate the limits of 'normal' potassium/rubidium ratios. In view of the close coherence of potassium and rubidium in a wide variety of igneous, metamorphic and sedimentary rocks (as well as chondritic meteorites and tektites), variations in the potassium/rubidium ratios beyond the normal limits indicate extreme processes, capable of fractionating potassium and rubidium (providing that the analyses are of satisfactory precision and accuracy).

Relative enrichment in rubidium has long been known from the special geological environment of large pegmatite bodies[2,5]. This has usually been ascribed to extreme magmatic or metamorphic differentiation causing the 10 per cent difference in ionic radius between K^+ (1·33 A.) and Rb^+ (1·47 A.) to become effective. The points lying in area I of Fig. 1 represent analyses of alkali feldspars from some large pegmatites. Recently, the same trend has been recognized in some rhyolites and granites which have crystallized from highly fractionated magma[6]. The analyses of these rocks fall in area II of Fig. 1.

Relative impoverishment or depletion of rubidium has occasionally been noted in rocks (Ahrens, personal communication; Upton, personal communication; Heier, unpublished results) and some published results of Tolmachev and Filipov[7] indicate high potassium/rubidium ratios in nepheline[5].

Recent work at Oxford has provided definite anomalously low rubidium values in several alkali feldspars. In view of the established potassium/rubidium coherence these few abnormal potassium/rubidium ratios indicate unusual conditions. These analyses fall in area III of Fig. 1.

The feldspars which have abnormal ratios come from arendalite (=charnockite) near Arendal, South Norway (full circles, Fig. 2), and syenites and monzonites (crosses) from granulite facies rocks at Langøy, Lofoten Islands, Northern Norway. These feldspars are mesoperthites[8].

In Fig. 2 the calculated orthoclase (*Or*), albite (*Ab*) and anorthite (*An*) values for these feldspars are plotted. The shaded area represents the composition of about eighty alkali feldspars with normal potassium/rubidium ratios. This figure is a projection of the quaternary system $NaAlSi_3O_8$(*Ab*)–$KAlSi_3O_8$(*Or*)–$CaAl_2Si_2O_8$(*An*)–H_2O at 5,000 bars water pressure[9]. Analyses are plotted as weight per cent *Or*, *Ab* and *An*. The cotectic curve separating the fields from which *OrAb*-rich feldspars and *AbAn*-rich feldspars crystallize out is indicated.

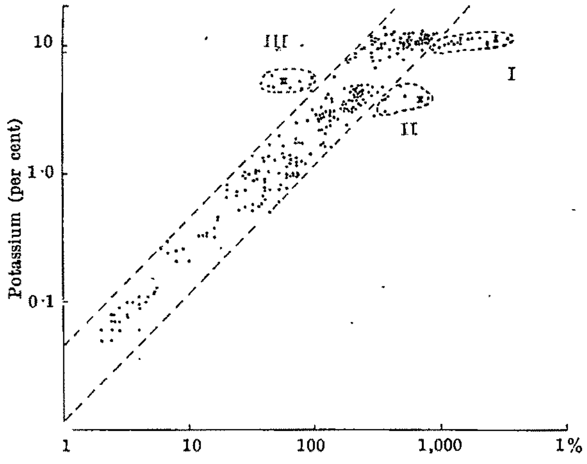

Fig. 1. Potassium–rubidium relationship for rocks and meteorites. Dashed lines indicate limits of scatter of 'normal' potassium/rubidium ratios. Area I includes feldspars from large pegmatites showing enrichment in rubidium; area II includes granites and rhyolites enriched in rubidium (ref. 6); area III includes feldspars depleted in rubidium

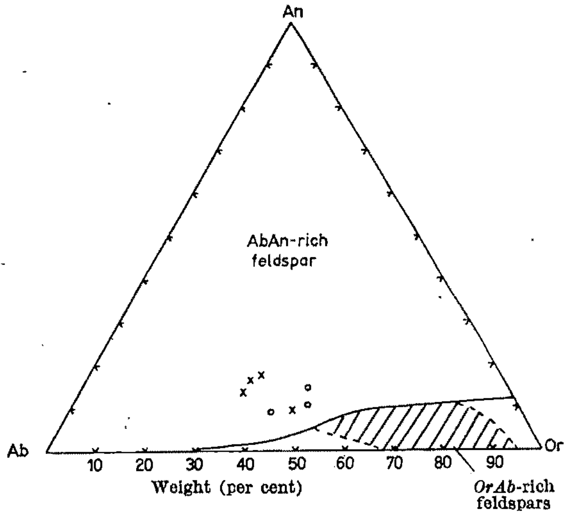
Our results indicate that rubidium is preferentially excluded from alkali feldspars, which, although containing substantial amounts of potassium, have a composition which places them in the *AbAn*-rich field of Fig. 2, but close to a composition from which an *OrAb*-rich feldspar would crystallize as a stable phase. It is of interest to note that the *AbAn*-rich feldspars impoverished in rubidium lie close to the maximum of the subsolidus curve for alkali feldspars separating the one and two feldspar regions, indicating maximum instability for a single feldspar phase. Where an *AbAn*-rich phase separates, the number of co-ordination sites available for potassium must be



Key: ○ Arendalite; ×, Syenites–monzonites Langøy

Fig. 2. Feldspar compositions plotted on the projection of the quaternary system $NaAlSi_3O_8$(*Ab*)-$KAlSi_3O_8$(*Or*)-$CaAl_2Si_2O_8$(*An*)-H_2O at 5,000 bars water pressure (ref. 9). The shaded area represents the composition of about 80 alkali feldspars with normal potassium/rubidium ratios

restricted. In this case, the 10 per cent difference in size is liable to become critical, and K^{+} may preferentially enter the lattice at the expense of RB^{+}. If much Ba^{2+} (1·34 A.) is present this may also occupy the high co-ordination sites to the exclusion of rubidium. This hypothesis for rubidium depletion implies that the feldspar crystallized as a homogeneous phase, and that in these cases the mesoperthite structure is due to unmixing and not to replacement.

It should be noted that a purely structural explanation for the exclusion of rubidium cannot be completely valid, since plagioclase feldspars have normal potassium/rubidium ratios. (This is indicated by the normal ratios of basic and intermediate igneous rocks, and also by the few analyses of plagioclase feldspars available.)

The additional factor seems to be the concentration of potassium in the system from which the feldspar is crystallizing. In the cases where rubidium is depleted, the system has a composition very close to the point where an independent *OrAb*-rich feldspar will appear as the stable phase. Potassium is thus very abundant and may be thought of as 'forcing' itself into the crystal lattice, which has a restricted number of sites for large ions. Rubidium, present in much smaller amounts and at a size disadvantage in this competition, will be excluded in favour of potassium in this somewhat unusual case.

Invertase Activity in Clay Mineral - Soil Mixtures

It has been demonstrated that clay minerals can inhibit several enzymes. For example, adsorption of yeast invertase on kaolinite produces a partial inactivation of the enzymic activity, which however continues slowly[1]. By adsorption of yeast invertase on bentonite at *p*H 2·9 the enzyme is rapidly inactivated[2]. The activity of nuclease is also reduced in presence of bentonite[3]. Montmorillonite, illite and kaolinite inhibit several phosphatases[4]. McLaren has also reported that adsorption of enzymes on kaolinite may lead to a reduction or complete loss of their activity[5]. Cellulase and hemicellulase activity is reduced in the presence of montmorillonitic clays[6]. From these experiments, suggestions have been made of the possible role of the inhibition of enzymes by clay minerals in the hydrolysis of organic compounds in soil, and in humus formation.

Soil, such as clay minerals, adsorbs enzymes such as jackbean urease[7] and yeast invertase[8]. It has also been observed that added enzyme (wheat bran phytase) is not inactivated by soil[9]. The original phosphatase content of the soil suffers no reduction in its activity when clay minerals are added to soil[10]. My previous investigation[11] showed that the original natural invertase of the soil, like phosphatase, undergoes no inactivation in clay mineral – soil mixtures; on the contrary, I observed a very much increased invertase production in these mixtures, induced by the specific enzyme substrate (sucrose).

If, in these clay mineral – soil mixtures, the original natural invertase content of the soil is protected from the inhibiting action of the clay minerals, then it is still uncertain if this protective effect of the soil is a general property and so valid also for an added invertase preparation.

This problem has been studied with a neutral degraded chernozem soil (humus content 4·27 per cent), kaolinite (*S* value, 9·60 m.equiv./100 gm.; *T* value, 18·90 m.equiv./100 gm.), bentonite (*S* and *T* values, 55·60 m.equiv./100 gm.), and a yeast invertase preparation. One series of samples contained clay minerals in different quantities plus a constant volume of the yeast invertase solution; another series contained clay minerals in different quantities plus a constant quantity of soil (20 gm. air-dry soil) plus a constant volume of the yeast invertase solution. As controls, we used soil alone and yeast invertase alone. To all samples toluene was added to suppress microbiological activity, buffer solution (2 *M* Na_2HPO_4 / 2 *M* CH_3COOH, 1 : 1) at *p*H 5·5, and sucrose solution as enzyme substrate. Incubation was for 4 hr. at 37° C. The rate of inversion was determined polarimetrically. For obtaining clear solutions for polarimetry, our previous procedure was used[12]. For polarimetry we used a 2-dm. tube with light from a sodium lamp, and a temperature of 20° C. Invertase activity is expressed as the difference between rotations before and after incubation. No adsorption was observed of the sucrose or its hydrolysis products by the clay minerals, soil or the mixtures used. The results of the invertase activity determinations are given in Fig. 1.

It can be seen that the clay mineral – soil mixtures, like soil, have only a minimal inhibiting action on the yeast invertase; the attenuation of the activity of yeast invertase by the clay minerals is prevented by adding soil to the clay minerals.

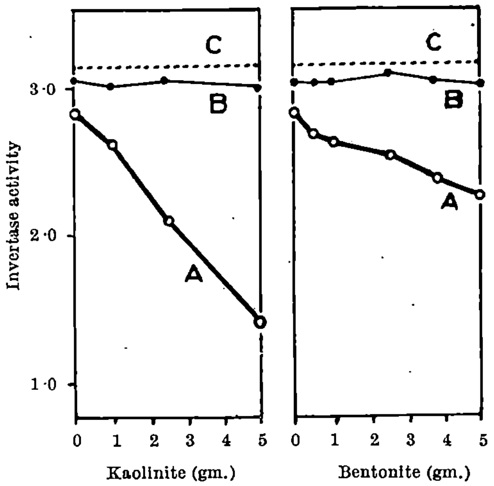

Fig. 1. Activity of yeast invertase in the presence of clay minerals, *A*, and of clay mineral – soil mixtures, *B*. The straight line *C* represents the sum of the activities of the soil invertase alone and of yeast invertase alone

This work indicates that data on enzyme inhibition by clay minerals cannot be applied directly to processes in soil because of its protecting effect.

The Middle Cambrian Trilobite *Centropleura* in Queensland

THE trilobite genus *Centropleura* Angelin 1854 was established for a Swedish species, *Paradoxides lovéni* Angelin 1851. *Centropleura lovéni* occurs in the Middle Cambrian Andrarum limestone of Scania, Sweden. During the century that followed its first discovery, the genus was found in rocks of the same Middle Cambrian age on Bennett Island in the Arctic Ocean, in northern and eastern Siberia, in the United States in the State of Vermont, and in Canada in the eastern part of the Gaspé Peninsula. It was assumed that *Centropleura* was an 'arctic' and 'subarctic' trilobite.

In all these localities *Centropleura* is rare and is preserved as fragments unsuitable for reconstructing the exoskeleton. Angelin published a reconstruction that has been reproduced from time to time in the subsequent literature. This reconstruction is still incomplete and is, apparently, based on two different species. An almost complete specimen of a related form ("*Anopolenus*") was described from Great Britain. Although this specimen is strongly sheared, it shows an organization different from Angelin's reconstruction of *Centropleura*.

In 1952 and 1954, two species of *Centropleura* were found in Middle Cambrian sediments in Queensland, 6 and 15 miles east from Duchess. One species (the older) occurs in shale and is fragmentary. The other species occurs in limestone and is well preserved. It is slightly younger than the first and is found in the Devoncourt Limestone, the age of which is uppermost Middle Cambrian. This age is indicated by the presence of *Leiopyge laevigata* in the Limestone.

From the Devoncourt Limestone numerous fragments and a complete specimen of *Centropleura* were recovered. It is a new species closely related to the Swedish *Centropleura lovéni* (Angelin). The reconstruction of this new species is shown in Fig. 1.

The occurrence of *Centropleura* in tropical Queensland and south of the present equator disposes of the idea of an arctic trilobite with its geographical distribution controlled by climate. The scattered distribution of *Centropleura* merely indicates that the seaways were open almost the world over in Cambrian time.

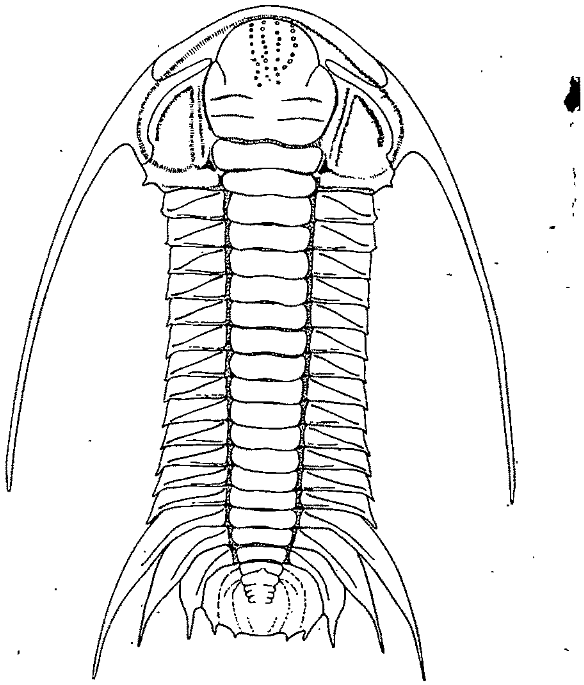

Fig. 1. *Centropleura* n.sp. (reconstruction one-third natural size); Devoncourt Limestone, Queensland

Centropleura, as seen from the reconstruction (Fig. 1), deviates in its organization from other trilobites in several ways. Its three posterior thoracic segments are macropleural and are linked with each other and with the pygidium into a rigid, non-articulating unit. This 'pygidial unit' functioned even as a moulting unit, although after moulting it could disintegrate into its four original components. The rigidity of the unit results from the backward curvature of the line of contacts between the posterior tergites, whereas flexibility along the contacts is possible only where they are straight hinge lines, as is seen between the remaining thirteen segments and the cephalon. These thirteen segments also have unusual short pleuræ with an extremely narrow doublure. The hour-glass shape of the thorax is unique.

A rostral shield fused with the hypostoma is also preserved.

Centropleura is at present assumed to be a genus of the family Paradoxididae. Its expanded glabella and the character of the posterior glabellar furrows may support this view. However, the structure of the thorax and of the pygidium, the deep interlocking of the free cheeks and cranidium, and the advanced position of the cephalic spines, including the intergenal spines, do not support the assumption of a close relationship between *Paradoxides* and *Centropleura*.

A complete description of the new species of *Centropleura* and the associated fossils is in preparation and will be published in a forthcoming bulletin of the Bureau of Mineral Resources, Geology and Geophysics.

This communication is published by permission of the Secretary, Department of National Development, Canberra, A.C.T.

RTHCOMING EVENTS

(*Meeting marked with an asterisk * is open to the public*)

Monday, July 21

Palæontological Association (in Meeting Room J, Royal School of Mines, Prince Consort Road, London, S.W.7), at 2.30 p.m.—Prof. T. N. George: "Evolution and the Palæontological Record".

Wednesday, July 23—Wednesday, July 30

Royal Microscopical Society (at the Polytechnic School of Photography, 309 Regent Street, London, W.1)—"Micro 58": an Exhibition of Photography with the Microscope.* (July 23rd, Fellows and Invitation only.)

Thursday, July 24

Royal Society of Tropical Medicine and Hygiene (at the Hospital for Tropical Diseases, 4 St. Pancras Way, London, N.W.1), at 7.30 p.m.—Clinical Meeting. Chairman: Brigadier J. S. K. Boyd, O.B.E., F.R.S.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Lecturer in Agricultural Economics—The Registrar, The University, Manchester 13 (July 23).

Assistant Lecturer in Physical-Organic Chemistry—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (July 23).

Lecturer (with a good degree in chemistry and appropriate teaching, research or industrial experience) in Spectroscopy, for duties which will include teaching spectroscopy to Diploma in technology and Degree standard and special postgraduate courses for industrial chemists—The Principal, Brunel College of Technology, Woodlands Avenue, Acton, London, W.3 (July 25).

Assistant Lecturer in the Department of Physiology—The Registrar, The University, Liverpool (July 26).

Assistant (with a first- or second-class honours degree in biochemistry or chemistry) in the Department of Biochemistry—The Secretary, The University, Edinburgh (July 26).

Engineers, Chemical Engineers or Physicists (at least 26 years of age, with a good university degree, or Corporate Member of a senior engineering institution, and preferably industrial experience), for training as Reactor Technologists—The Recruitment Officer, United Kingdom Atomic Energy Authority, Industrial Group Headquarters, Risley, Warrington, Lancashire, quoting Ref. 2476 (July 28).

Assistant Lecturer in Mathematics—The Registrar, University College of Wales, Aberystwyth (July 31).

Head of the Department of Mathematics and Physics (Grade B), Kumasi College of Technology—Council for Overseas Colleges of Arts, Science and Technology, 12 Lincoln's Inn Fields, London, W.C.2 (July 31).

Sir Alan Cobham Research Fellow in Aeronautics to carry out research in one of the following subjects: (*a*) aircraft noise and structures, (*b*) hypersonics, (*c*) helicopter vibrations, (*d*) jet flap investigations, or (*e*) numerical methods applied to wing design—The Secretary and Registrar, The University, Southampton (August 1).

Research Worker in Psychology—The Registrar, The University, Sheffield (August 2).

Demonstrator in Physiology—The Registrar, King's College (University of Durham), Newcastle-upon-Tyne (August 6).

Lecturer/Senior Lecturer (preferably with some experience in the field of aeroelasticity) in Aeronautical Engineering at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, August 9).

Lecturer (with a university degree in engineering or science at honours level) in Electrical Engineering at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, August 9).

Clinical Veterinary Pathologist (with experience in all veterinary pathological investigations) at the University of Sydney Veterinary Hospital at Camden, for duties which will include the diagnostic examination of clinical material, teaching and research—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, August 15).

Lecturer (with an honours degree in physics, preferably able to teach the subject to a high standard, and with teaching, industrial or research experience) in Physics—The Principal, Wigan and District Mining and Technical College. Wigan (August 15).

Lecturers (2) in Psychology at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, August 15).

Senior Lecturer (with an honours degree in science) in History and Method of Science at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, August 15).

Research Fellow (with a Ph.D. degree in the relevant branch of chemistry with some additional experience, preferably with the Group 8 elements) in the Biological Inorganic Chemistry Unit, John Curtin School of Medical Research, Australian National University, to carry out fundamental research on the synthesis of co-ordination compounds of the heavier transitional elements—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, August 19).

Lecturer (with at least an honours B.Sc.) in Zoology at the University of Cape Town, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa, August 30).

Research Assistant (with an honours degree in biochemistry or pharmacology), to work on the biochemistry of hypoglycæmic sulphonamides—The Department of Pharmacology and Therapeutics, Queen's College (University of St. Andrews), Dundee (August 30).

Lecturer (with an honours degree or a higher degree in chemical engineering or equivalent qualifications, and preferably an interest in mass transfer) in Chemical Engineering at the University of Canterbury, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, August 31).

Lecturer or Senior Lecturer in History and Philosophy of Science at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, August '31).

Senior Lecturer in Inorganic and Analytical Chemistry at the University of Natal, Durban—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa, August 31).

Non-statutory Lecturer in Physical Chemistry—Prof. T. S. Wheeler, Department of Chemistry, University College, Dublin (September 1).

Professor of Horticulture—The Secretary and Bursar, University College, Dublin (September 1).

Reader in Fluid Mechanics at the Imperial College of Science and Technology—The Academic Registrar, University of London, Senate House, London, W.C.1 (September 11).

Head (with at least a first-class honours degree in botany, agricultural botany or equivalent and preferably with suitable postgraduate research experience) of the Department of Plant Physiology—The Secretary, The Grassland Research Institute, Hurley, Near Maidenhead, Berks (September 15).

Lecturer in Pure Mathematics—The Registrar, The University, Hull (September 15).

Assistant (Grade B) to teach Chemistry with some Physics or Mathematics—The Principal, North-West Kent College of Technology, Miskin Road, Dartford, Kent.

Assistant Lecturer in Crop Husbandry, and an Assistant Lecturer in Agricultural Chemistry—The Principal, Seale Hayne Agricultural College, Newton Abbot, Devon.

Assistant Lecturer in Mathematics—The Secretary, The Royal College of Science and Technology, Glasgow.

Experimental Officer (not under 26 years of age, with at least H.S.C. (Science) or equivalent and extensive experience in metallurgical analysis, including the analysis and control of trade waste effluent, and preferably several years supervisory experience), to be responsible to the Laboratory Manager for the work of a small team engaged on general inorganic chemical analysis—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berkshire, quoting Ref. A/1736/34.

Lecturer/Demonstrator in the Chemistry Department—The Bursar, Royal Agricultural College, Cirencester.

Reader (with a degree of a British university and research qualifications in some branch of applied mathematics or statistics) in Applied Mathematics—The Clerk to the Governing Body, Battersea College of Technology, London, S.W.11.

Research Students in Organic and Inorganic Chemistry—The Secretary and Registrar, The University, Southampton.

Scientific Officer (with a first- or second-class honours degree in mathematics, science or economics) at the Building Research Station (D.S.I.R.), Garston, Watford, for work in a section dealing with information and publicity through exhibitions, press, etc., secretarial work for home and European scientific committees, patents, and general central administration on scientific matters—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.242/8A.

Senior Lecturer or Lecturer in the Department of Aerodynamics, for lecturing to, and supervising work of, postgraduate students in the field of stability and control—The Recorder, The College of Aeronautics, Cranfield, Bletchley, Bucks.

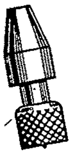
Abundance of Pogonophora.—Dr. A. J. Southward	272

"BELLING-LEE" SUB-MINIATURE *Components*

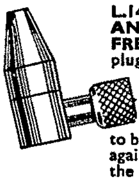
Sub-miniature coaxial plugs and sockets have been designed to meet requirements for small coaxial connectors brought about by the increase in the development of miniaturized equipment.

P.T.F.E. insulation is used and all contact surfaces are gold-plated for low resistance connection. A knurled nut securely retains plug to threaded socket, with rubber washer fitted to prevent loosening by vibration.

Suitable for use with B.I.C.C. Cable, No. R.P.C.1373



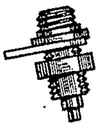
L.1403/FP. FREE PLUG. The cable to this plug enters along the axis of the plug. The rubber cover protects the cable clamp from damage and gives the plug a streamlined appearance.



L.1403/RFP. RIGHT ANGLE ENTRY FREE PLUG. This plug has the cable entry at right angles to the axis of the plug, enabling the cables to be "dressed-down" against a panel without the danger of sharp bends causing cable failure.

ILLUSTRATIONS ACTUAL SIZE

L.1403/BS. BULKHEAD ADAPTOR. This socket-to-socket panel mounting adaptor provides for the passage of a coaxial cable through a panel, in such a way that the cable can be disconnected on either side. It is ideal for use where a coaxial lead needs to be continued behind the main panel of equipment.



L.1403/CS. CHASSIS MOUNTING SOCKET. This socket is designed for use where the feeder enters equipment, and is not required to continue as a coaxial cable, as the components associated with it are in close proximity to the socket. It is fitted with soldering tags which are gold-plated for ease of soldering.

These components and other new developments are fully described in the Supplement to our General Catalogue: copies are available on request.

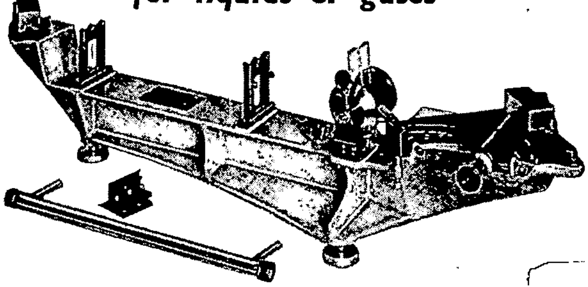
PRECISION B&S INSTRUMENTS

Jamin Refractometer

for liquids or gases



Average accuracy in measurement of refractive index is approximately 0·000001 for gases and 0·000002 for liquids.

The elimination of all spring adjustment to the mirrors results in great stability and freedom from vibration. Worm wheel gearing actuates the compensator. Tubes up to 50 cm. length can be used.

THE STRUCTURE OF RESEARCH IN BRITAIN

IN an address on the role of government in science at the annual dinner of the Institute of Physics on March 26, Lord Hailsham expressed the opinion that many of the thorniest problems of political life would be dealt with in a more wholesome and practical way if solved by the pragmatic sanctions of technical requirements than if pursued as a doctrinal issue by *a priori* argument. While without Government support much essential scientific work would no doubt remain undone, the role of Government in science is inevitably unsatisfactory because science, a subject beyond all else jealous of its integrity, must pursue its courses without political interference.

The main theme of his address was the necessity for a close partnership between Government and science, and in discussing this question Lord Hailsham affirmed his belief that, although the risk of waste is always present in research, neither in fundamental nor in applied research are we in Britain, as a nation or as individuals, in danger of spending too much. Speaking as Lord President of the Council, Lord Hailsham claimed that the system of research councils under the Lord President places civil research in the hands of scientists themselves, and Government responsibility is discharged largely by patronage, in the old and good sense of the word, by interest, co-ordination and, to some extent, by initiative, vision and enterprise. Lord Hailsham recognized very clearly that the selection of the right projects and the decision when to extend, continue or to terminate them are the crucial problems in research, and that they demand a constant influx of young and active minds. He stressed, too, the significance of appropriate conditions if research is to be an attractive career; and he mentioned also the importance of egress as well as entry, and the value of constant cross-fertilization between research institutions and user and teaching bodies.

Lord Hailsham did not comment on the adequacy or otherwise of the Government contribution of some £225 million to the national expenditure of £300 million annually on research; he said he is convinced that, viewing scientific research simply as an investment, the industrial and private contribution could with advantage be considerably increased. He also believes that too little use is made of the published results of research. On the whole, Lord Hailsham thinks we have achieved the right balance in our administration or control of research; but, in a concluding reference to the industrial research associations, he appealed for greater interest in them by the industries they serve, and for the co-operation of the trades unions. Coupled with the indication in the subsequent report of the Council for Scientific and Industrial Research that Government policy in regard to the research associations is under review, although the Council has not yet reached final conclusions, and with some criticism of the electrical industry which Lord Hailsham made on another occasion, this has led to some speculation as to whether the Government is minded to wind up the research associations.

There are large issues involved in any such policy; but apart from this, Lord Hailsham's complacency scarcely seems justified in the light of the recent report of the Research Council (see *Nature*, June 14, p. 1623). Moreover, Dr. G. B. B. M. Sutherland's remarks as an introduction to the annual open days at the National Physical Laboratory suggest doubts as to whether, in fact, we have achieved the right balance in the organization and control of research. Dr. Sutherland emphasized the potentialities of the Government research stations, which, when well led, can and should be a jump ahead of industry. He claimed that the value of the work at the National Physical Laboratory to the national economy is at least as great as that of Harwell, but he was obviously dissatisfied with the way in which Government control is exerted. Few research projects have been terminated for lack of money, but it would appear that Treasury control has been exercised in such a way as to infringe the independence or integrity of science, which Lord Hailsham recognizes as of such outstanding importance.

In contrast to Lord Hailsham, Sir Hugh Beaver, a former chairman of the Advisory Council for Scientific and Industrial Research, in his presidential address to the Institution of Chemical Engineers on April 30, was frankly critical of the adequacy of present arrangements in Britain to make full use of the resources of science in the service of the State. Sir Hugh was concerned in this address mainly with the educational aspect and with the financing and organization of research, though he touched very briefly on the question of seeing that the results of research are both known and applied, and also on the assistance of development. The key problem is that of education, and here he showed convincingly that there is, in fact, no national policy to produce an adequate supply of scientists and technologists, or even the national organization to secure an educational policy. Even more impressive, coming from a former chairman of the Advisory Council, is the criticism of the Government structure for the organization of research, and particularly of the Department of Scientific and Industrial Research. Sir Hugh asserted that the bulk of Government research or of research sponsored by the Government does not come under the Lord President at all. Besides defence research and that on nuclear energy under the Atomic Energy Authority, any Government finance for the aircraft industry will presumably continue to come through the Ministry of Transport and Civil Aviation or the Ministry of Supply, and important research is carried out under the Ministry of Power; while the contribution of the Department of Scientific and Industrial Research to research in the universities of Britain, the recognized home of fundamental research, now runs at half a million pounds annually, with grants to students—which might be taken as contributing something to that purpose—exceeding £800,000, compared with a recurrent grant of about £50 million provided through the University Grants Committee.

The activities of the National Research Development Corporation and of the Patent Office seem ancillary to research rather than a part of the national research effort, but in noting that the work of those bodies comes under the Board of Trade, Sir Hugh Beaver was really directing attention to the way in which responsibility for the scientific effort of the nation is distributed over numerous departments, and that the tendency to regard the Lord President as an approximation to a Minister for Science is misleading and ill-conceived. His point that no means exist either for formulating or securing a co-ordinated national policy of research or for directing the many research activities in Britain to desired ends is incontestable, and it tends to be concealed when the Lord President is made the spokesman for the scientific activities of the Government generally, even if indirectly. Further, Sir Hugh, pointing out that the Department of Scientific and Industrial Research could be described as largely a common service research department for other Government departments, remarked that there is still a wide division of opinion as to whether the various Ministries should have their own research departments or depend on the Department of Scientific and Industrial Research. The Select Committee on Estimates has sometimes been severely critical of departmental research, but the question still seems to be unresolved.

Finally, Sir Hugh Beaver suggested that by its organization the Department of Scientific and Industrial Research is virtually without a ministerial head. He did not advance any constructive suggestions here, and although his words seem to imply that the Department should be given wider responsibilities for research, he questioned whether the recent changes have made the Department suitable in form and in methods for discharging duties which its title envisages. He does not think that the Lord President of the Council is in the appropriate position to direct the scientific thinking and planning which we need to formulate a coherent policy capable of handling all the four aspects involved, namely: education, or the production of the scientists and scientific leaders; the encouragement and support of research and the allocation of research workers; the dissemination and application of the results of research; and the problems of finance. Nor does he favour the idea of a Minister of Science with such over-riding powers as the Minister of Defence possesses, even if to some extent such a Ministry would be consistent with the present position of the Ministry of Defence.

Neither Sir Hugh Beaver's address nor Lord Hailsham's speech takes us as close to the root of the matter as the discussion of scientific research in the recent survey of the organization of British central government made by a Study Group of the Royal Institute of Public Administrators, or Lord Waverley in his Romanes Lecture of 1946. Both are of value, however, as indicating certain aspects which the Council of Scientific and Industrial Research should have in mind in the survey of the work of the Department on which it is now engaged. The limitations to which Sir Hugh has directed attention should not affect the Council's consideration of the contribution of the Department to fundamental research, or the part which its own stations can play in industrial and applied research. For all those limitations, the Department is in a position to bring a wider perspective to bear than most other organizations, and to make a significant contribution towards redressing the balance of effort and avoiding duplication and waste. Moreover, Sir Hugh did not show why the responsibilities of the Lord President should not be extended in the field of science and less relevant duties curtailed, particularly if the Office were adequately and appropriately staffed.

It is clearly desirable that some means should be found for improving on the present haphazard and illogical manner in which the Government attempts to discharge its responsibilities towards science, though a completely formal and unified structure may not be the right answer. It is important, however, that, while inquiry and fresh thought as to the best and most appropriate means for ministerial responsibility and guidance to be exercised proceeds, care should be taken not to endanger the advantages which the present arrangements possess. Among those advantages the functions of the Department, in respect of both university awards and research grants and also the industrial research association system, are outstanding. However much direction at ministerial level may be improved, the value of such an independent stream of research grants will remain, and it would become even more difficult to correct weaknesses or to meet some recognized needs in university research if all Government grants for such purposes flowed to the universities in a single stream. It should be noted that the recent report of the U.S. National Science Foundation on the relations between central government and universities strongly emphasized the value of a diversity of government sources of support for university and fundamental research.

Again, while the industrial research association may not be the appropriate arrangement for every industry, and indeed in some circumstances could, by its very success, make a research association in a particular industry no longer necessary, it has become clear that the research associations in Britain are also performing very useful educational functions, quite apart from their work in furthering the dissemination of the results of research and stimulating its application. It is true that, in respect of applied research, the research association is at an inherent disadvantage compared with the research department of an individual firm; but in almost every industry there are likely to be projects which are most economically and efficiently tackled by co-operative effort. Such factors require close consideration in determining the future of the industrial research associations, and their contribution to technical and technological education must be carefully weighed in considering the supply of scientists, technologists and technicians and the educational policy required to produce them.

It is essential, therefore, that the Council for Scientific and Industrial Research should formulate very clearly its ideas as to the exact functions of the research associations and of the Department's own research stations and institutions, and that their advantages and disadvantages should be fully discussed before any decisive change is made in the present system. It is by the appropriate use of a wide range of types of institution rather than by a rigid and formal structure that weaknesses in research are best corrected, and while it is important that every effort should be made to see that these institutions are as efficient as possible and appropriately used, it should not be forgotten that success primarily depends upon men.

This point was made by Prof. R. S. Nyholm in a recent broadcast on university research and its financial needs. After stressing the desirability of varied sources of finance, and particularly the desirability of sources of finance over and above that received from industrial organizations and research institutions, in which he referred to the value of the help received from the Department of Scientific and Industrial Research, Prof. Nyholm said that he is convinced that unless we put a much greater effort into fundamental research Britain will face serious problems in a few years time, because our position in the world twenty years hence would be determined by the fundamental research of to-day. Prof. Nyholm was particularly concerned with the calibre of the scientists whom we are losing to the United States and to other countries, partly at least because the opportunities for fundamental research, the equipment and the salaries offered are better than in Britain.

Prof. Nyholm was discussing primarily the financial aspect ; but he believes that Britain can hold its best people and still attract the best from abroad if it will continue to lay emphasis upon that most precious privilege of the university, namely, freedom to do what one likes—which implies to-day the finance with which to do it. Lord Hailsham seemed to recognize this ; but while the appropriateness of our whole structure for research receives examination and the relations of the different types of research institution are being reconsidered, there is much the Government could do to promote the conditions which will attract the ablest minds into research and enable them to give of their best. Nor is it simply a matter of attracting the scientist or technologist into research ; it is equally important, as Sir Hugh Beaver noted, to produce scientific leaders.

This is a matter to which post-war Governments in Britain, whatever their political party, and however they may have professed their concern with the supply of scientists and technologists and their support of research, have in practice been consistently indifferent. Mr. Stanley Mayne's address to the delegate conference of the Institution of Professional Civil Servants on May 19 recapitulated some recent instances of the way in which lack of vision, clear purpose and vigorous resolution are cramping and devitalizing the scientific development of Britain. To his catalogue of examples, including the failure to make use of the Royal Ordnance factories, difficulties in connexion with aeronautical research, university finance and railway transport, and the failure of the Atomic Energy Authority to intensify recruiting and build up staff in accordance with recommendations of the Fleck Committee, could be added others, notably in the parsimony displayed towards the National Science Centre and all the projects for developing an adequate system of national lending and references libraries for science and technology.

All this obviously arises from the failure on the part of Government to appreciate the bearing of such factors on the effectiveness with which scientific work is carried out and the efficiency with which its results are made known and applied. Until genuine attention is given at Cabinet-level to the effect of society on science, the way in which obsolete forms of organization, lack of knowledge, political prejudice and the like frustrate the use of science and the development of technology, changes in the organization of the means of central direction are likely to have little effect. Decisive action by Cabinet Ministers who really understand the significance of science and technology and the conditions in which good work is done most effectively would go far to remove many of the existing hindrances, and to promote more effective use of trained man-power and other scientific and technical resources. To such matters as scientific and technical libraries might be added the control of the Patent Office, the taxation of learned societies, tax allowances for books, and questions of postage and publication, all of which can influence decisively the efficiency of communication. Such matters require no fresh forms of organization but merely people at Cabinet-level able to comprehend the issues and resolute to take the necessary action.

It is once again a matter of education, ultimately long-term but requiring also a short-term effort, if Britain is to have any real prospect of developing her scientific and technological potential. The recent report from the Council of Scientific and Industrial Research suggests that important issues of the organization and structure of research have already been raised in the Council's relation to the Agricultural Research Council and the Medical Research Council ; and the Minister of Supply's recent statement on aircraft research indicates another direction in which the question of structure has assumed fresh importance. So, too, in the field of nuclear research, where not only Sir Hugh Beaver's address but also recent addresses on the development of the industry accentuate the importance of achieving an appropriate balance in the use of man-power and materials for research, and suggest doubts as to whether in fact the Council for Scientific and Industrial Research is the appropriate body to establish that balance.

Sir Hugh Beaver has rightly directed attention to weaknesses in our structure for research which merit fresh inquiry and constructive thought as a matter of urgency. Even more important, he has emphasized the close relation of the whole question of research, its organization and the provision made for its pursuit with that of education, not simply for the production of scientists and technologists, or even of the supporting technicians, upon whom the efficient use of highly trained man-power largely depends, but also of educational policy as a whole—a policy which is concerned both to produce scientists and technologists and the citizens and administrators capable of appreciating and supporting their work. The unity of education and research in relation to science and technology could not be better put. Imperative as it may be to devise appropriate arrangements for providing effective scientific and technical advice at all levels, from the Cabinet downwards, to make the fullest possible and most appropriate use of the wide range of research institutions at our disposal, to further efficient co-operation between government departments, industry, the universities and other independent research institutions, and the professional organizations of scientists and technologists, the key problem is that of education. The promotion of the expansion of scientific, technological and technical education is not enough by itself; it must be accompanied by the development of an educational system and policy which will equip men and women to live in this technological age, and will produce not simply the essential specialists but also leaders, from ministerial level downwards, aware of the human as well as the technical issues and capable of the vision and the resolution required to make full and wise use of the powers now at the command of mankind.

ADVANCES IN NUCLEAR ENGINEERING

Advances in Nuclear Engineering

Proceedings of the Second Nuclear Engineering and Science Conference held at Philadelphia. Edited by John R. Dunning and Brice R. Prentice. Vol. 1: Pp. vii+523. Vol. 2: Pp. vii+581. (London and New York: Pergamon Press, 1957.) 147*s*. net each volume.

THE International Congress on Atomic Energy held in Geneva, 1955, opened the door, closed for fifteen years, to scientific and technical information about fission and nuclear reactors. In spite of the 1,000 papers published then, there was an enormous amount of material not presented at that time, and, of course, since that time technology has proceeded apace in the many branches of applied science embraced within nuclear engineering. These volumes record the proceedings of the Second Nuclear Engineering and Science Conference held in Philadelphia, March 1957, and comprise 130 papers on reactors, fuel and a few other matters, almost all the papers being of American origin. Many of the papers amplify the Geneva subjects—such as details of the Hanford waste disposal, recovery of uranium from the Oak Ridge diffusion plant, plutonium extraction plant, etc.; many more take us forward from Geneva, such as the consideration of irradiation of liquid bismuth containing uranium, consideration of containment vessels, and the analysis of safety standards to be adopted in ships carrying reactors.

Vol. 1 opens with two papers which are interesting to read a year after they were written. A member of the U.S. Atomic Energy Commission, referring to the British nuclear energy programme based on an average cost figure of 350–400 dollars per installed kW. for the complete power stations being built by industry, remarked that these figures appeared to be materially higher than those estimated for the Yankee pressurized water reactor; alas, only in October, at the Twelfth American Assembly, the cost of the Yankee station is estimated to be more than 550 dollars/kW., and that may not include the complete power station (the Shippingport 60-MW. reactor appears to cost 1,000 dollars/kW. for the reactor portion alone). The speaker also expressed satisfaction over the fact that America had more export orders for research reactors than any other country; but is it hard to sell such reactors if the sale also includes the gift of the whole or half of the cost of uranium-235? One of the "Three Wise Men" wisely said at the Conference, "Again, Europe needs your help, but . . . our relationship will not be that of one country giving and another receiving, but of two great united nations (the U.S.A. and U.S. Europe) working in association".

Vol. 1 contains many papers on the refining of fuels, processing after irradiation, and economic consideration of fuel cycles. Some papers concern experience with the technology of reactors already in operation, others deal with the projected reactors, such as the thorium/uranium breeder reactor, the continuous removal of fission products from molten bismuth containing 0·1 per cent fuel, and a speculative paper on the economics of ceramic fuel elements operated at temperatures far higher than any fuel in operation to-day. There are many papers on pressure vessels, and pipes and other components which have to withstand high pressures or contain molten sodium, and a fairly detailed paper on the Enrico Fermi 100-MW. fast breeder reactor now being built to operate at 880° F. Almost all the large reactors now being built in America will be surrounded by a steel containment vessel of the order of 200 ft. in diameter for which there is at present no design code, and the section on plant containment is full of important information.

There is a long section on the disposal of radioactive wastes. No method now exists, says one writer, which is both cheap and permanently satisfactory. Fixation of fission products in clay is attractive, but over long periods of time it is difficult to predict the probability of water reaching the burial ground of the clay, and leaching out the long-lived elements. A Canadian paper reports some success in fixing wastes in a lime glass which would then be buried in dry ground—adding 0·1 mil/kWh. to the cost of electricity. The facilities for dealing with the wastes from the Shippingport reactor are described; here the water becomes radioactive due to corrosion and at times of maintenance is removed from the reactor but may not be dumped into the Ohio River. Ion exchange resins have been chosen, and the solution is regarded as satisfactory, simple and economical: the resin reduces non-volatile radioactivity by a factor of 1,000 and a 'gas-phase stripper' removes activity of a further 10^6. Active resins are then stored presumably in perpetuity. Anticipated costs are not given for this treatment, although in a companion paper the capital costs are spoken of as being high.

In the section on protection and safety measures there are two papers which should be read carefully by people having responsibility for health measures in atomic plants; they concern the three basic standards of maximum permissible exposure, the last of which, dealing with total absorbed dose up to age thirty and thereafter, has only been adopted in the past year. The effect of this third recommendation is effectively to reduce the average occupational dose-rate by a further factor of 3, now to 0·1 rem/week. Dr. Lauriston Taylor's article carefully analyses the effect of these new levels on radiation control problems. An analysis of the hazards of the application of nuclear power for ship propulsion seems to show that these are distinctly greater than will be encountered with land-based stations; from a safety point of view the ship power plant ought to use low-pressure coolant, but all the submarines so far employ the pressurized water reactors operating at thousands of pounds per square inch pressure. The writer does not favour the gas-cooled reactor "when the power plant is mobile and open to collisions".

The provision of facilities for irradiating food is discussed in several papers, although no new major advance is reported on the art or science of food processing. The U.S. Army is sponsoring both electron accelerators and a γ-source (a reactor) to support research on the subject, and Brookhaven has designed a cobalt irradiator of high power. There is an interesting description of the medical research programme using the Brookhaven research reactor; the article concludes with the remark that the irradiation of diseased sites in which elements having high neutron affinity have been selectively absorbed is one of the most important uses of the reactor and is expected to remain so for a long time to come.

In Vol. 2 will be found important engineering papers on problems of some of the large power reactors such as the 175-MW. engineering test reactor at Idaho, the 20-MW. sodium-cooled reactor, the Oak Ridge homogeneous reactor which has exhibited extensive stress corrosion cracks in austenitic steel tubing and flanges, the 60-MW. breeder reactor (EBR 2) for which performance tests on individual items of construction are quoted, and the pressurized water reactors for which a considerable body of operating experience now exists. Some remarkable results on the behaviour of suspensions of uranium oxide in liquid metals are given for the first time, and there is more information on the polyphenols as possible coolants for power reactors. There are many papers on research reactors; several of our university reactor courses have fully realized the importance of instruction being given at the reactor face, and the Oak Ridge School of Reactor Technology, which has had more experience of reactor teaching than anywhere else in America, firmly advocates such teaching supplemented with reactor experimentation. In these papers will be found accounts of many experiments which can be formed on quite low-powered reactors.

There are many papers on the metallurgy of reactor constructional materials and fuels, pure and alloyed. Some results of neutron irradiation of common pure metals—non-fissionable—do not agree with Russian work reported at Geneva. The metals investigated in the Materials Testing Reactor (MTR) for three weeks hardened but did not exhibit changes in microstructure. Hanford metallurgists report on the mechanical properties of uranium after irradiation at various temperatures; the results indicate the extreme importance of optimum design of fuel elements if trouble due to distortion is to be avoided. The mechanical and anti-corrosion properties of uranium alloys with small additions of molybdenum and other elements together with ternary elements have been studied in many laboratories, but unfortunately no work is presented on irradiation damage to these alloys with the exception of one paper on pressed powder compacts of uranium and of a few of its simple alloys. It is interesting to note that even hot-pressed compacts considered at the time of Geneva to be randomly oriented have now, however, been shown to be sufficiently oriented to develop substantial dimensional changes upon irradiation, and the sintered alloy compacts swell as fast as, or faster than, unalloyed specimens. The general conclusion of several authors at the Conference was that much more work on alloys at high burn-up should be done before the best of them can be applied to reactor design.

Reactor instrumentation is a very important subject considered by one section of the Conference. One paper suggests that reactor instrumentation can now be regarded as conventional, needing only to be matched with the requirements of the reactor, but in general the papers show that many new instruments are being developed to cover a wide range of measurements. Even the common resistance thermometer has been given a new look to withstand 5,000 lb./in.^{2} for use in the pressurized water reactors. An ultrasonic flowmeter with an output signal independent of temperature of either water or of hydrocarbon fluid is one of the most original instruments described, and there are important contributions to neutron flux and positron life-time measurement. There is a strong plea put in for standardization of instruments in such a way as not to stultify the development of them, but no indication is given of what has been achieved by way of standardization to date.

The volumes are very well produced and all figures are adequate. The achievement of publication within six months of the Conference is commendable, especially as the volumes are printed and not produced by one of the modern off-set methods. The Conference has not made the mistake which I consider was made by the 1955 Geneva Congress—that of publishing the author's spoken presentation of the paper in addition to the paper, and the discussion which followed.

T. E. ALLIBONE

ANATOMY OF MATHEMATICS

A History of Mathematics

From Antiquity to the Beginning of the Nineteenth Century. By Dr. J. F. Scott. Pp. xii+266+6 plates. (London: Taylor and Francis, Ltd., 1958.) 63*s*. net.

A HISTORY of mathematics up to A.D. 1800 in 216 pages of main text can scarcely be more than an epitome. Dr. Scott spares us the trivial if amusing gossip about personalities, and concentrates on tracing the lines of development of the subject; an appendix contains brief biographical notes on some 120 great mathematicians. But even so, there is little enough room for a comprehensive account. Dr. Scott's earlier studies have been chiefly concerned with the seventeenth century, and in his book this century occupies one-third of the main text. Consequently, some other periods receive sketchy treatment: the eighteenth century is given very little of the detailed discussion of method accorded to the previous century. If it is argued that the eighteenth century mathematicians merely exploited the creative ideas of their predecessors, the book might well have ended with the death of Newton.

The Greek period is given generous space. Dr. Scott's estimates of the debts the Greeks owed to the Egyptians and the Babylonians would not be universally accepted, and the general reader might well consult van der Waerden, "Science Awakening", for the somewhat different view presented by that great Dutch mathematician. On Greek mathematics itself, there is much useful and clear description, with comments that are sometimes misleading. For example, to remark of the parallel postulate, "It is not that anyone questions the truth of it: the important point is that it is not self-evident, as an axiom should be", after saying that "alternative geometries could be devised in which this postulate plays no part", may cause the unwary reader to suppose that non-Euclidean geometries are false. Moreover, this comment ignores the distinction drawn by the Greeks between the axiom or 'common notion' and the postulate or special assumption, which the student is asked to grant, not to accept as a 'self-evident truth'. Again, we are told that Archimedes had no idea of proceeding to a limit, but argued that if an area did not have measure k, then a contradiction must follow; this obscures the fact that for this argument to work, we must first know k, and it seems likely that Archimedes sometimes obtained k by a limit process, which was then suppressed in writing out the final synthetic demonstration.

It is with the seventeenth century that Dr. Scott gets into his full stride. His enthusiasm for the great mathematicians of that era, his wide knowledge of the material, his careful description of methods combine to provide an account which at times gives a sense of the excitement of discovery. Napier's logarithms, Descartes' marriage of algebra with geometry, Newton's binomial theorem are all most attractively described. The futile controversy between Newton and Leibniz over the invention of the calculus is briefly dismissed with the sensible remark that there is no sound reason against believing the discovery to have been made independently and more or less simultaneously. But the author is perhaps a little too generous to the forerunners, Cavalieri, Fermat, Barrow, and others; the step from their knowledge to that of Newton and Leibniz is more critical than Dr. Scott allows, and reference for a lucid and precise discussion of this point may be made to an article by Hadamard in the Royal Society's volume, "Newton Tercentenary Celebrations".

There are some excellent plates: the Rhind papyrus, pages from Barrow's "Euclid", Oughtred's "Clavis" and Stevin's "Statique", and two pages of the famous letter in which Newton describes the steps which led him to the discovery of the binomial theorem.

T. A. A. Broadbent

THE PROVINCE OF LOGIC

The Uses of Argument

By Prof. Stephen Edelston Toulmin. Pp. vii+261. (Cambridge: At the University Press, 1958.) 22*s*. 6*d*. net.

This book contains an interesting and provocative discussion of the philosophical issues about the nature of logic. Toulmin considers that logic traditionally has as a main object the study of argument; but, he maintains, logic has tended more and more to become a mathematical discipline the relevance of which to an understanding of the principles of argument is hard to discern. The root cause of this partial failure of logic is diagnosed as an excessive regard for the analytical type of argument found in pure mathematics combined with a desire that logic itself should have formal rigour. Logicians, therefore, have failed to see, or have neglected, the fact that most of our arguments, scientific, moral or legal, are not of this analytical type and cannot be judged valid or invalid, convincing or unconvincing, by the same criteria of logical evaluation as are the analytical arguments of mathematics. Such terms as 'valid', Toulmin holds, are general terms of evaluation, the criteria for the application of which vary systematically according to the type of argument under consideration; but formal logic has been so preoccupied with analytical argument that the criteria for the application of evaluative terms of logic to analytical arguments have been taken to be the unvarying meaning of those terms in all contexts. Toulmin considers that if we are to throw light on the nature of argument we must clearly recognize that different criteria of logical merit apply to different kinds of argument and seek to bring these criteria to light by a study of actual argument.

In his second chapter Toulmin gives an extended specimen of the kind of study of argument that he is advocating by an examination of the notion of probability. He argues very plausibly that the attempts of Carnap and Kneale to analyse the concept of probability against the background of the traditional approach to logic are unsuccessful; then, making use of a valuable distinction between improprieties and mistakes in assertions, he maintains the thesis that to say 'probably p' is to assert p (with the consequent risk of being mistaken) but to assert p *guardedly*, as is appropriate when grounds for assertion are weak, thus evading the impropriety of bald assertion in such circumstances. Toulmin maintains that this interpretation of probability is applicable even in such contexts as seem most favourable to a frequency interpretation; but it is hard to see that "The probability of throwing heads is $\frac{1}{2}$" is a guarded statement, or, if it is, what form of words one would use to make the same statement in an unguarded way.

Toulmin also offers a new schematism for the description of arguments. He recommends us to think of data, warrant and conclusion rather than of premisses and conclusion. Thus we could say that from the datum that Socrates is a man we conclude that Socrates is mortal with "All men are mortal" as our warrant; or we may conclude that Petersen is probably not a Roman Catholic from the datum that he is a Swede, with "Few Swedes are Roman Catholics" as our warrant. Toulmin argues persuasively in favour of some such redescription of argument; but it is not entirely clear what this distinction between a warrant and a datum is: How would one know which of two universal premisses in a syllogism was datum and which warrant?

With modesty Toulmin claims to have raised problems rather than to have solved them. Anyone with an interest in the study of argument in real life, not merely in formal logicians' theorems, will find here much to interest him, something to convince him and, in all probability, something to provoke him to argument.

J. O. Urmson

SUBMICROSCOPIC MORPHOLOGY

Macromolecules in Cell Structure

By Prof. A. Frey-Wyssling. (The John M. Prather Lectures, 1956.) Pp. vii+112+13 plates. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1957.) 40*s.* net.

THERE is evidence that the Prather Lectures on which this book is based were actually delivered at Harvard in 1955, which, in a subject that is advancing so rapidly, detracts a little from a presentation in 1957, but it will none the less be warmly welcomed by the numerous admirers of Prof. A. Frey-Wyssling's pioneer researches and earlier contributions to the literature. It is a handsome little book, and the electron micrographs especially, on which so much of the argument depends, are very well reproduced.

The emphasis and the topics chosen are naturally mostly botanical—the fine-structure of starch grains and chloroplasts, and the fine-structure, growth, and differentiation of plant-cell walls—but a necessary wider background also is provided by a chapter on "Macromolecules in the Cytoplasm". The approach throughout, as is to be expected in a set of special lectures of this kind, is distinctly personal, and this extends to many of the references and some of the text-figures. For example (p. 1): "I have called this new field of investigation *Submicroscopic morphology*. In the early days we used polarizing microscopy for this research (Ambronn and Frey, 1926), but soon X-ray diffractometry brought welcome support (Frey-Wyssling 1937*a*), and since 1944 electron microscopy (Frey-Wyssling and Mühlethaler 1944, 1946) has raised submicroscopic morphology to a generally recognised standard science". Such historical over-condensations are in the cause of saving space, but newcomers might misconstrue them, I am afraid.

Though Prof. Frey-Wyssling's favoured technique these days is electron microscopy, of which he has made most valuable use, he concedes that the older methods of polarizing microscopy and X-ray analysis are "still useful" (p. 5), and indeed ranges over and seeks to co-ordinate all kinds of information, as the reader will find to his ever-widening profit. There is no narrow way of looking at the structure of biological tissues, and no shallow way either. We continue uncovering finer and finer constituents, but the picture appears still much the same in the depths. Prof. Frey-Wyssling makes this point repeatedly, as when, for example, he remarks, "this special architecture must be the result of the morphogenetic work of the cytoplasm. Mere mechanical considerations cannot explain the inception of any differentiation" (p. 36); and "The bordered pits are a beautiful example of the morphogenetic capacity of the cytoplasm" (p. 48); and as regards the cytoplasm itself, so optically empty no longer ago than the early 'thirties, I particularly like his summarizing comment: "As a result of this discussion we find that the term cytoplasm is defined by the negative property of comprising that fraction of the living substance that escapes our morphological analysis" (p. 71).

I would commend, too—out of so many other points of agreement or controversy that one could raise without the least difficulty in so rich a field—his discussion of the corpuscle–fibre paradox and related questions. Man-made fibres, invented on the basis of tricks picked up primarily from Nature's workshops, are spun from more or less drawn-out chain-molecules, yet it turns out now that Nature herself seems to proceed more often than not by first stringing together unit packets of coiled and folded chains.

There are a few misprints and anomalies in spelling and grammar, and I must confess to having been peculiarly saddened to read 'flagellae' four times over.

W. T. Astbury

A KEY TO LEAF-MINING INSECTS

Bestimmungstabellen der Blattminen von Europa

Einschliesslich des Mettelmeerbeckens und der Kanarischen Inseln. Von Prof. Erich M. Hering. Band 1: Pflanzengattungen A-L. Erzeuger Nr. 1—3133. Pp. 648. Band 2: Pflanzengattungen M-Z. Erzeuger Nr. 3134—5551. Pp. 535. Band 3: Neubeschreibungen von Minen-Erzeugern Systematische Ubersicht der Wirtspflanzen und der Minen-Erzeuger. Abbildungen. Pp. 221 (86 tafeln). (The Hague: Dr. W. Junk, 1957.) Complete set, three volumes, 180 guilders. [About £18.]

LEAF-MINING insects feed on plant leaves, not by biting pieces out of them (like most caterpillars) but by destroying either the pallisade tissue or the spongy parenchyma, or both. The 'mines' are of very diverse forms, and are often characteristic of the species of insect which causes them. As a rule the damage, though unsightly, and such as to impair the efficiency of the leaf as a functional organ, is of little economic significance. However, some crops may, from time to time, be seriously damaged, so the group is potentially dangerous. Thus the mangold fly, whose larvæ can usually be found in any field mining the leaves of sugar beet, often does little damage to the crop, but it may cause losses exceeding three tons per acre. Agricultural and horticultural entomologists often find leaf-mining insects or observe the damage they cause, but identification of the insects often presents serious problems. Coleoptera, Hymenoptera, Lepidoptera and Diptera all have species with the leaf-mining habit, but this habit may be confined to one member of a family, and similar damage may be caused by widely separated species of insects.

In the first two of the volumes here considered the various host plants are listed alphabetically, and there is then given for each plant a key listing all the mining insects, with a brief description of the damage they cause. The author has interpreted his subject rather liberally, so some insects which might be considered as gall producers are listed here as miners, but this adds rather than detracts from the value of the book to most users. 5551 instances of mining damage are listed. The keys are well and simply laid out, so those who do not read German easily should be able to use them without difficulty.

Vol. 3 lists and describes a dozen new species of leaf-mining Diptera, and one new lepidopteran. It includes a list of the food plants, and of the families of insects involved. 170 pages contain 725 line drawings, mainly featuring the damage caused to plants by these insects. The figures are quite well drawn and reproduced.

These volumes will be a useful tool to agricultural entomologists and others, but it is a pity they could not have been produced more cheaply. The printing and paper are good but the books are poorly bound in flimsy paper covers. Notwithstanding the usefulness of the contents they seem expensive at eighteen pounds for the set of three modest volumes.

KENNETH MELLANBY

TRAINING MANAGERS

New Ways in Management Training

A Technical College Develops its Services to Industry. By Cyril Sofer and Geoffrey Hutton. Pp. xii + 127. (London: Tavistock Publications, Ltd., 1958.) 15*s*. net.

CONCERN to make his department of more value to industry in the training of managers led Robert Harcourt, head of the Department of Management and Production Engineering at the Brunel College of Technology, to initiate the study which is described in this book. The objects of the study were to examine the function and possibilities of a department of management and production engineering in servicing industry, how industry could make known its wants and needs as well as the way industry could help the department. The task was entrusted to the Tavistock Institute of Human Relations and, in collaboration with members of the Brunel College staff, was carried out during 1954–56.

While their report on this valuable investigation will be of interest to their fellow social scientists, Sofer and Hutton's account is likely to be of more direct value to training officers, educational administrators and many industrial managers. It will be of even greater relevance to those responsible for the control and development of technical colleges.

To set the study in its right background, an account is given of the place of the technical college in the national educational system and its place *vis-à-vis* the universities and other organizations in the training of management for industry. This is followed by details of the kinds of students who attend management courses at technical colleges, together with reasons as to why they attend. These are sometimes illuminating. Most of those who were studying for management certificates, for example, saw their courses as in some way a contribution to their personal advancement; most of the management students expected to get better jobs with employers other than their own. Few students had really high ambitions and a not infrequent comment was: "I don't think I'll ever get to director level because you need social connections for that. Somebody who is likely to finish up at that level would not have come from a technical college, but would have taken a Cambridge degree".

One of the great weaknesses of technical college classes is borne out by the finding that most students did not expect to find discussions with fellow students very helpful to learning. Each student's contact with others was said to be minimal: "Hardly any friendships were developed within the class and very little discussion of course material took place spontaneously. . . . At the end of the evening everybody went home—they were tired and hungry".

The attitudes of firms in Acton to technical colleges and their staffs can be regarded as typical for the whole of Great Britain. Although educational and scientific pursuits rank fairly high as social activities in Britain, the status of technical colleges among them is low; they are thought to serve a less-important purpose than more 'academic' institutions, and to be concerned more with training in specific craft skills than with the preparation of young people for life or for positions of social leadership and responsibility. Teachers in technical colleges are regarded more as school teachers than university lecturers, and as persons of mediocre calibre. The technical college teacher was thought to be insufficiently appreciative of production management, 'up in the air' and over-theoretical; it was often said that a man who really knew management and could practise what he preached would be a manager, not a teacher. Larger firms felt no need for the services of management and production engineering departments except for a limited amount of junior supervisory classes and for management courses of the conventional type; smaller firms made demands for courses in the organization and supervision of production and in general education.

The rest of the book describes how Sofer and Hutton and their collaborators attempted to find a way through this wall of prejudice. After considerable resentment had been dissipated, the teachers began to understand that the views of the industrialists were not wholly distorted; the industrialists began to realize that under their noses was a most valuable service if they cared to use and contribute to it. Detailed surveys were carried out in firms to show how the department could be of greater value to them and, eventually, separate advisory panels were formed to make a permanent link between the College and industry. Finally, members of the Tavistock Institute of Human Relations were asked to organize a course to help the teachers to become more expert in dealing with students from industry and industrial affairs. It needs little reading between the lines to appreciate that this was far from successful and that the approach of the academic social scientist in teaching teachers has considerable limitations.

Of the study as a whole, not much need be written. Harcourt and all those concerned at the Brunel College of Technology deserve applause for their courage and perspicacity in initiating the project. The Tavistock Institute of Human Relations should be congratulated for the way it saw and grasped an opportunity to improve the quality of management education at Acton and elsewhere. Sofer and Hutton are to be warmly commended for carrying out a difficult survey in an objective and discerning manner and for recording it so intelligibly. This is so out of keeping with other publications of the Tavistock Institute that it scarcely seems possible that this book could have been produced under its auspices. By this important work Sofer and Hutton have not only made a contribution to the development of better management education at technical colleges, but may also have reconverted leading industrialists to the belief that the Tavistock Institute really has a contribution to make to the solution of many industrial problems.

T. H. HAWKINS

New PERGAMON Books

Vapour-Liquid Equilibrium

by EDUARD HÁLA, JIRI PICK, VOJTECH FRIED *and* OTAKAR VILÍM, *Department of Physical Chemistry, Institute of Chemical Technology, Prague, Czechoslovakia. Translated by* Dr. G. STANDART.

This book is intended for workers in the chemical industry who have to deal with problems of distillation and rectification. It should help them in design, development and the rational operation of distillation equipment by showing how to obtain the necessary equilibrium data and numerical results.

Price 90s. net ($14.00)

Surface Phenomena in Chemistry & Biology

by J. F. DANIELLI, *Ph.D., D.Sc., F.R.S., Professor of Zoology, King's College, London.* K. G. A. PANKHURST, *Ph.D., D.Sc., F.R.I.C., Packaging Research and Development Division, Reed Paper Group.* A. C. RIDDIFORD, *Ph.D., Lecturer in Chemistry, University of Southampton.*

This is a collection of essays and articles on surface phenomena in chemistry and biology written by active workers in the field from many countries, compiled as a tribute to Professor N. K. Adam on his retirement from the Chair of Chemistry at the University of Southampton, in appreciation of his contributions to the study of surface phenomena.

Space-Charge Waves

AND SLOW ELECTROMAGNETIC WAVES

by A. H. W. BECK, *B.Sc.(Eng.), A.M.I.E.E., Standard Telecommunications Laboratories Ltd.*

This book sets out to present a unified treatment of the small-signal behaviour of microwave valves, which term is used in its broadest sense and comprises the frequency range from roughly 1 kMc/s to the highest frequencies which can at present be generated as coherent radiation. The author writes not as a scientific historian but as an active research worker who has developed along with the subject and this book should be a valuable addition to the literature.

items of interest from our laboratory notebooks

The unique properties of Toluene-3 : 4-dithiol have drawn attention to the potentialities of dithiols in the analytical field. Now comes **Quinoxaline—2 : 3—dithiol** as a quantitative reagent for nickel at the 0.03 to 3.0 p.p.m. level. (**Anal. Chem.**, 1958, **30**, 365) and for the detection of Ni in qualitative analysis (R. E. D. Clark, **Analyst**, in the press). This is all very recent work but the reagent is ready (H. & W. Code 7393).

We have added so many metal indicators (for EDTA titrations) to our range since the last edition of our catalogue that we hesitate to pick on any one for special mention. The most recent was **Naphthyl Azoxine** (H. & W. Code 5959) for Cd, Co, Cu, Pb, Ni and rare earths (see **Anal. Chem.**, 1957, **29**, 821), but we have most others already in stock.

Nitrosoresorcinol monomethyl ether is a comparatively new colorimetric reagent for iron and cobalt. There are others, of course, but S.M. Peach (**Analyst**, 1956, **81**, 371) considers that this one has some particular advantages. For instance, the Co complex can be extracted into an organic solvent. The reagent will appear as an addition (H. & W. Code 6303) in our next catalogue amendment.

La Lutte contre *Stephanoderes hampei* Ferr.

Par G. Schmitz et P. Crisinel. (Série Scientifique, No. 70.) Pp. 156. (Bruxelles: Institut National pour l'Étude Agronomique du Congo Belge, 1957.) 130 Belgian francs.

THE coffee berry borer beetle, *Stephanoderes hampei*, is one of the important pests of a tropical crop, and its control by insecticides has been reconsidered since the development of chlorinated hydrocarbons and organic phosphorus compounds. Primarily a pest of *robusta* coffee, this small Scolytid was introduced into South America and the East Indies in early consignments of seed from tropical Africa. It causes shedding of the developing coffee cherry and damage to the bean.

Schmitz and Crisinel give the results obtained between 1950 and 1955 in controlling *Stephanoderes* on a field scale in the north-east of the Belgian Congo. Trials were carried out with a number of chemicals, including DDT, BHC, dieldrin and parathion. These were applied in a wide variety of ways from hand dusting and spraying to power-operated machines. The best results under prevailing local conditions were obtained with an endrin emulsion and a power-operated atomizer, 'Swissatom 2000', for which operating costs are given in detail.

The fact that successful pest control depends on a thorough knowledge of the pest is recognized by the authors, who devote nearly half their paper to establishing the background against which they had to work. A historical survey of *Stephanoderes* as a pest of coffee, supported by a detailed bibliography, is followed by an account of its life-history, and by a statement of the problem from the point of view of coffee production. The whole problem of 'shedding' as found in plantations in Uele is discussed in relation to the proper diagnosis of the part played by *Stephanoderes vis-à-vis* fungus attack and physiological disturbance of the coffee bush.

The Institut National pour l'Étude Agronomique du Congo Belge and the Compagnie Cotonnière Congolaise are to be congratulated in collaborating in establishing this work on so wide a basis. Schmitz and Crisinel have, in consequence, produced a report which will be of great value to those interested in the wide field of crop protection in the tropics.

W. V. HARRIS

Chromatographic Techniques

Clinical and Biochemical Applications. By Dr. Ivor Smith. Pp. xiii+309. (London: William Heinemann Medical Books, Ltd., 1958.) 45*s*. net.

THIS is rather different from the general run of books on this subject. It is confined mainly to the application of paper chromatography to substances of clinical interest. No attempt is made to cover the innumerable methods; instead, one single apparatus for one- and two-dimensional separations is described and a minimal number of solvent systems and location reagents of proved usefulness have been selected. Opening chapters deal with apparatus and give a full account of the methods of desalting and preparing fluids for chromatography. Chapters then follow, each devoted to recommended procedures for preparing chromatograms of amino-acids, sugars, barbiturates, indoles, steroids, phenolic acids and so on, in human blood, urine and tissue fluids. Some of these chapters include very useful sections on clinical interpretations of chromatograms in disease. Final chapters give guidance for further investigations of unknown constituents observed on chromatograms and describe model experiments for students. The uniform style of the chapters reflects careful editorship and close collaboration with the various authors. The result is an attractive book, which within its limits contains a tremendous amount of information most attractively presented; it should prove of the greatest value for research workers in clinical chemistry, and because it has sought to standardize methods it should stimulate the wider adoption of paper chromatography for routine clinical chemical purposes and even encourage the general practitioner to use the method.

R. CONSDEN

Stedman's Medical Dictionary

Edited by Norman Burke Taylor in collaboration with Lieut.-Col. Allen Ellsworth Taylor. Nineteenth revised edition. Pp. xlvi+1656. (London: Baillière, Tindall and Cox, Ltd., 1957.) 88*s*.

THIS weighty volume provides brief definitions of many thousands of medical, dental, veterinary, chemical and botanical terms, together with notes on their derivation and pronunciation. Short biographical sketches of outstanding figures in medical history are included. A separate, 36-page section on medical etymology precedes the main work, and this most informative contribution should be of the highest value to medical students unversed in Greek and Latin. An appendix contains, among other useful data, comparative tables of weights and measures, temperature and barometric scales, and anatomical nomenclatures.

The dictionary itself satisfies the essential requirement of any medical dictionary, that it be reasonably comprehensive, accurate and lucid. It is not free from mistakes and misleading statements; on p. 787 "splenomedullary" leukæmia is described as the commonest form of leukæmia, with marked leucocytosis, "large uninuclear eosinophile myelocytes predominating"; acute leukæmia is not listed as such; under "hemoglobin" only three abnormal forms are mentioned; and in many minor respects definitions are sometimes not in keeping with current beliefs. Blemishes of this sort are inevitable in so massive a work, and are, of course, confined chiefly to subjects in which medical advance has been rapid. A more serious drawback for the British reader is the American spelling, regrettably often different from that used in this country, which renders the dictionary unsuitable for use by medical secretaries and typists.

F. G. J. HAYHOE

Observations on Birds of Southeastern Brazil

By Margaret H. Mitchell. Pp. x+258+11 plates. (Toronto: University of Toronto Press; London: Oxford University Press, 1957. Published for the Division of Zoology and Palæontology, Royal Ontario Museum.) 45*s*. net.

THE birds of South America and their taxonomy are very well known; very little has been recorded on what the birds look like and how they behave in their natural surroundings, and what these surroundings are. This book is a valuable collection of field observations on 289 species occurring in south-eastern Brazil. The author resided in Rio de Janeiro for four years and had opportunities of visiting the adjacent States. Field identifications were checked against specimens in the São Paulo State Museum and with the aid of Dr. Olivério Pinto. Although mainly concerned with field study, Mrs. Mitchell did not neglect to become conversant with relevant literature and the text is annotated with more than 100 references. The style is pleasantly informal and very easy to read.

MEASUREMENT OF THE ENERGY SPECTRUM OF PROTONS EMITTED FROM THE FUSION REACTION IN SCEPTRE III

By W. M. JONES, A. C. L. BARNARD, S. E. HUNT and D. R. CHICK
Research Laboratory, Associated Electrical Industries, Ltd., Aldermaston, Berks

DEUTERIUM fusion may proceed by two reactions, D(dp)^{3}H and D(dn)^{3}He, which occur with almost equal probability at low deuteron energies. Measurements on the energy spectrum of the neutrons emitted from ZETA have already been reported[1], but no measurements of proton energy have yet been reported from fusion reactions occurring in gaseous discharge systems.

If fusion is induced by deuterons having only thermal motion, the energy spectrum of the protons will be independent of the angle of observation, whereas if some process producing a preferred direction in the deuteron motion is involved, the proton energy will depend on the angle of observation with respect to the preferred direction of motion.

The present communication describes a preliminary investigation of the proton spectra from Sceptre[2] using cameras with nuclear emulsion plates inserted into the torus. The cameras protruded only slightly inside the walls of the torus and did not produce any measurable fall in the externally measured yield of neutrons, so that their presence did not appear to modify the discharge mechanism. They were arranged to accept protons emitted at nominal angles of 30°, 90° and 150° to the direction of flow of positive gas current. In order to prevent surface fogging of the plate due to low-energy radiation and light from the discharge, it was necessary to protect the plates by thin copper-foil windows.

The proton energies were estimated using the range–energy relationship for protons in Ilford *C*2 emulsion[3], a correction being applied for the loss of energy in the copper foil[4]. The measured dip angles and the theoretical shrinkage factor were used in deducing the range. Additional exposures were made at 90° using a camera of better geometrical definition, with which the angle of entry into the emulsion was known directly from the geometry. This permitted more precise absolute measurements to be made of the proton energies at 90°. The mean energy of this proton group was 3·03 ± 0·02 MeV., which shows that the protons originated in the (d–d) fusion reaction.

The proton yield estimated from the track density and camera geometry was consistent with the neutron yield estimated by external liquid scintillation counters. From the direction of the proton tracks in the 90° plates, it could

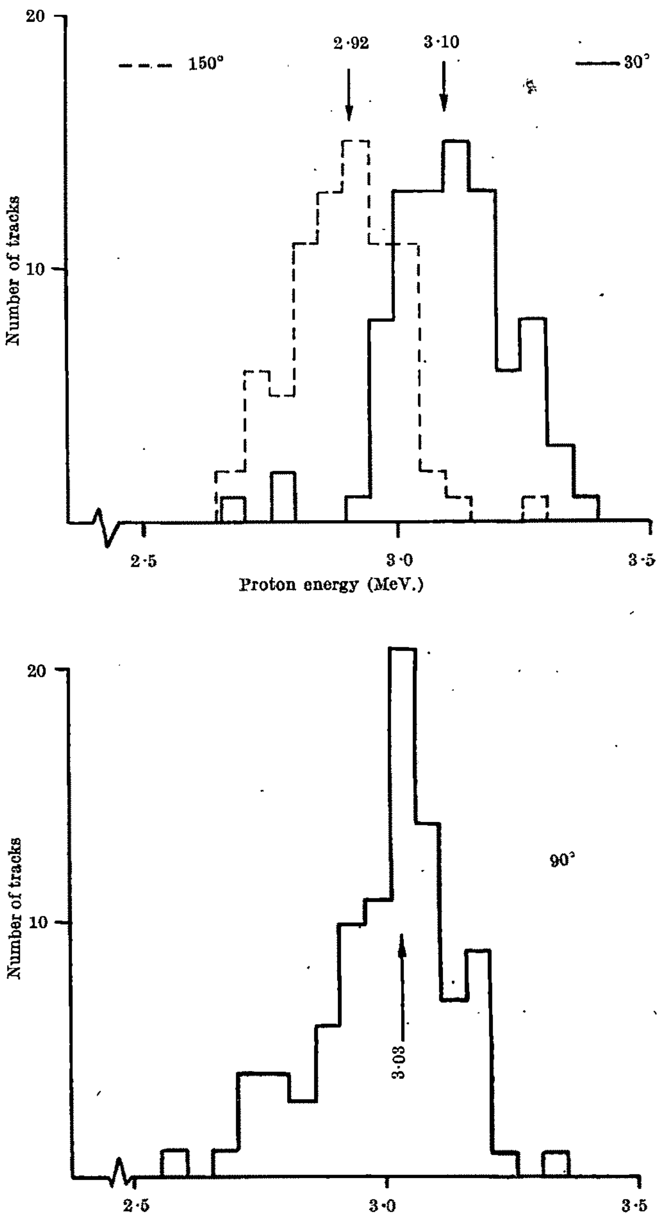

Fig. 1. Histogram of proton energy measurements at 150°, 30° and 90° to direction of positive gas current flow

Table 1. TORUS : SCEPTRE III

Date of exposure	No. of discharges	Deuterium pressure in torus	Condenser voltage (kV.)	B_z field (gauss)	No. of primary turns	Peak torus gas current (k.amp.)	Angle of observation	No. of proton tracks measured	Mean energy of proton group	Standard deviation	Estimated total error
31/5/58	4,477	1·4μ	25	500	16	100	30°	44	3·11	0·02	±0·03
16/6/58	5,000	1·4μ	25	500	16	100	30°	40	3·10	0·02	±0·03
20/5/58	7,980	1·4μ	25	500	16	100	90°	93	3·03	0·02	±0·02
11/6/58	5,900	1·4μ	25	500	16	100	150°	36	2·94	0·02	±0·04
15/6/58	5,000	1·4μ	25	500	16	100	150°	20	2·91	0·03	±0·04
17/6/58	5,400	1·4μ	25	500	16	100	150°	22	2·90	0·03	±0·05

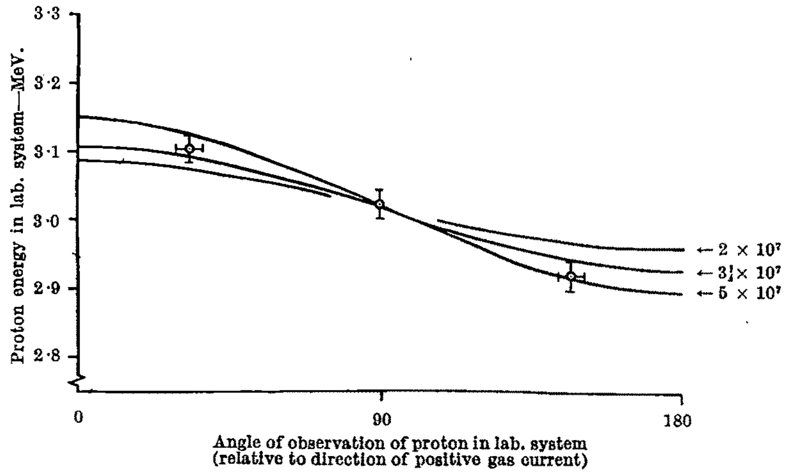

Fig. 2. Variation of mean proton energy with angle of observation

be deduced that most of these originated from the centre (one-third or one-half) of the discharge tube.

Energy spectra obtained at 30°, 90° and 150° are shown in Fig. 1. The energy values obtained for the three angles of observation are given in Table 1, together with the conditions under which the exposures were made. The errors were obtained by combining the statistical standard deviations with the errors associated with measurements of foil thickness and possible slight differences in density between the emulsions used in the measurements.

The results indicate that the majority of protons observed originate from fusion between deuterons the centre of mass of which has a velocity component in the direction of positive gas current flow. In Fig. 2 the observed variation of proton energy is plotted and compared with that calculated for deuteron centre-of-mass velocities of 2×10^7, 3×10^7 and 5×10^7 cm. sec.$^{-1}$ relative to the laboratory. The results give the best fit for a centre-of-mass velocity of about 4×10^7 cm. sec.$^{-1}$. This is less than the velocity of centre of mass indicated by the published results for ZETA[1].

We wish to thank the members of the Thermonuclear Section of this Laboratory and Mr. E. D. Taylor for their assistance in the experimental work, and Misses S. J. May and O. V. Lake, who scanned the plates. Thanks are also due to Dr. T. E. Allibone for his great interest and encouragement in this work and for permission to publish these results. The work has been supported in part by an Atomic Energy Research Establishment contract for thermonuclear research.

PEACEFUL USES OF ATOMIC ENERGY

SYMPOSIUM IN AUSTRALIA, 1958

A SYMPOSIUM on "The Peaceful Uses of Atomic Energy" was held in Sydney during June 2–6, organized by the Australian Atomic Energy Commission, the Australian universities, and a number of Australian industrial organizations.

The symposium was a major success and, in its stimulation of thought on matters related to atomic energy among all sections of the community in Australia, exceeded the hopes of even the most optimistic of its initiators. Several reasons have emerged for these results. The Australian Atomic Energy Commission's high-flux research reactor at Lucas Heights became divergent earlier in the year (see *Nature*, May 24, p. 1433); radiochemical and other laboratories have been commissioned and are being made ready to examine the products of the reactor when it is taken in some months time to its full power of 10 MW. Australian universities have introduced, or are considering, postgraduate courses in nuclear engineering and science. There has been a general increase in the tempo of nuclear research in universities, spreading from nuclear physics to other disciplines. Formal arrangements with the universities of Australia for their use of the facilities of the Lucas Heights Research Establishment have been made by the formation of the Australian Institute of Science and Nuclear Engineering. Under the stimulant of the Commission's isotopes advisory service, Australian industry has taken a rapidly increasing interest in the immediate applications of atomic energy. In the mining area, the uranium oxide production plants in Rum Jungle and Radium Hill are in full production, and the large plant at Mary Kathleen started production during the symposium.

With this background of atomic energy developments in Australia, a total of 435 delegates, including 38 from overseas, came to the symposium to discuss a total of 114 papers. The overseas delegates from the United Kingdom, the United States, Canada, France, New Zealand and Pakistan, particularly those countries well advanced in atomic energy developments, provided an energetic complement to the Australian contributions.

A considerable interest was displayed by the general public of Australia. A comprehensive atomic energy exhibition featuring displays from Australia and other participating overseas countries was well attended by members of the public. Prof. M. L. E. Oliphant's lecture to 2,500 school children was so popular that it had to be given in two sessions. A number of leading overseas scientists gave addresses on the radio and to scientific societies. Vigorous public questionnaire sessions from forums of local and overseas scientists were arranged as both 'live theatre' and television sessions.

The symposium was divided into five sessions: Section 1, Materials; Section 2, Power Engineering;

Section 3, Power Auxiliaries and Research Reactors; Section 4, Basic Sciences; and Section 5, Associated Techniques.

A period during the last day of the symposium was devoted to developments in the thermonuclear field. Dr. T. E. Allibone described the gas-discharge work at Harwell and at the A.E.I. Research Laboratories at Aldermaston. Dr. W. H. Pennington read a paper by Dr. A. E. Ruark describing the American programme. Prof. Oliphant discussed proposed experiments in Australia with the Canberra homopolar generator. These developments in thermonuclear experiments were of particular interest to Australia in that they gave a full account of the achievements and difficulties in this only recently declassified field.

Materials

The papers on materials can be divided naturally into two groups. The first dealt with minerals and ores containing uranium and thorium, with their occurrence in various parts of Australia, and with the several plants now operating for their extraction. The second group was concerned with actual or potential reactor materials, with their preparation and fabrication, and their properties.

In the first group there were papers dealing with the distribution of minerals important for atomic energy in South Australia (W. Johnson), in the Northern Territory (B. P. Walpole), in New South Wales (E. O. Rayner), and in Queensland (J. H. Brooks). These papers gave an up-to-date picture of the known deposits of ores of uranium and thorium in these States, with a good deal of information on the geology of the areas concerned.

One paper dealt with the instrumentation problems of the search for uranium and thorium (J. Daly and D. F. Urquhart). This covered the design of equipment for assaying and for prospecting, the latter use presenting the main problems. Equipment for use in moving vehicles and for bore logging, based on Australian experience, was described.

Australia's main uranium-producing plants were the subject of several papers. The production of uranium concentrate at Rum Jungle was described by Baker, and the somewhat different processes used at Radium Hill were described in two papers, the first (T. A. Rodgers) dealing with ore production and physical concentration, while the second (J. N. Arnold) dealt with the chemical extraction of uranium, and its recovery by ion exchange methods from the physical concentrates. A fourth paper (R. A. Couche and F. R. Hartley) gave a detailed account of the processes worked out for the recovery of uranium from the Mary Kathleen ores in Queensland. These papers brought out the differences in behaviour of the ores at these plants, all of which produce oxide concentrate of roughly the same type.

An important paper in this group was that entitled "The Jigged-Bed Ion Exchange Pilot Plant for Uranium Extraction", by G. L. Herwig, R. M. Stewart, E. A. Swinton and D. E. Weiss. It describes the plant and operating results, when extracting uranium from an acid pulp of low filtering properties, using a continuous ion-exchange process which does not require the pulp to be filtered. The process was used to treat experimentally one of the more difficult Rum Jungle ores.

The other half of this materials section consisted of nineteen papers. Australian interest in the development of the high-temperature gas-cooled reactor and the reactor fuelled with liquid metal was shown by a group of papers dealing with ceramic nuclear fuels, and problems relating to liquid metals. "Ceramics as Reactor Materials" (K. D. Reeve), "The Preparation of Thorium Carbide" (D. E. Scaife and A. W. Wylie), "Ceramics and Cermets Investigations" (L. S. Williams and J. Graham) were examples of such papers.

A considerable study of reactor materials, including graphite, zirconium and aluminium alloys and uranium dioxide fuel elements, was given in a paper entitled "Recent Progress in Reactor Materials Development" by F. N. Albaugh, R. E. Nightingale, E. A. Evans, J. W. Riches and R. L. Dillon.

The commercial process now adopted for the production of uranium metal in the United States was described by F. L. Cuthbert. The stages of leaching, solvent extraction, the production of 'green salt' and its reduction to uranium metal were all described. This paper also described the casting and machining or uranium and its alloys, and the recovery of the metal from process scrap.

On the technology of liquid metals, a paper by F. L. Bett was concerned with compatibility studies between liquid sodium and niobium, and a paper by H. M. Finniston dealt with corrosion in liquid-metal systems. This paper discussed the mechanism and kinetics of mass transfer in solid metal – liquid metal systems, such as may be encountered in reactors fuelled with liquid metal.

Other papers in this group dealt with the production of uranium metal powder by a hydriding process (J. W. Kelly), with the production of uranium metal powder by reduction with calcium of uranium oxide (R. H. Myers and R. G. Robins) and with the production of uranium metal powder by electrolysis (R. G. Canning). B. C. Woodfine presented a study of the materials problems in producing fuel cans for gas-cooled reactors, operating at higher temperatures than are used at present. He dealt with the magnesium alloys which are now favoured, and went on to discuss beryllium, carbon and stainless steel for this purpose.

The miscellaneous part of this section included papers on fusion welding of reactive metals (J. M. Newburn), irradiation effects on uranium and its alloys (H. M. Finniston), levitation heating (B. Harris, E. G. Price and A. E. Jenkins), neutron diffraction studies of compacts (T. M. Sabine and K. D. Reeve), materials for control of reactors (W. J. Wright and K. P. Nicholson) and studies of the lower halides of niobium and zirconium (I. E. Newnham).

The meetings of the materials section were marked by lively discussion throughout.

Nuclear Power Programmes

Section 2 covered papers on national atomic power programmes, specific power-reactor developments, and some papers on the economic questions that might be raised in the development of atomic power in Australia.

Five papers were presented on the national development of atomic power. They were: "The Nuclear Power Programme in the U.K." (H. H. Gott); "Development of Nuclear Power in the U.S.A." (L. H. Roddis); "The Canadian Nuclear Power Programme" (D. G. Hurst); "French Private Industry in the Atomic Field" (P. M. C. Retourna); "Possible Developments in Nuclear Fuel Cycles in Australia" (J. P. Baxter and C. N. Watson-Munro).

H. H. Gott's paper dealt briefly with the United Kingdom programme of installation of graphite-moderated natural uranium power reactors using carbon dioxide cooling. He discussed the advances that are taking place in the design and the development of these reactors and pointed out that the United Kingdom would only change to a significantly different type of reactor design if a new reactor could with considerable certainty generate power at a lower cost than those under construction.

P. M. C. Retourna outlined the contributions of French private industry to the French graphite-moderated natural uranium power reactors using gas cooling, and to the subsidiary industries such as graphite, calcium and zirconium production, chemical extraction and processing plant.

The extensive United States programme of reactor experiments, demonstration power reactors and full-scale power reactors was described by L. H. Roddis. He outlined the breadth of the American research and development programme in pressurized-water reactors, boiling-water reactors, sodium – graphite reactors, fast-breeder reactors, aqueous homogeneous reactors, organic moderated reactors, liquid-metal fuel and molten-plutonium systems and gas-cooled reactors.

D. G. Hurst outlined the programme of development of heavy-water natural uranium reactors in Canada and described the nuclear-power demonstration reactor under construction at Des Joachims. He described the conceptual design features of a 200-MW. (electrical) reactor under consideration by Atomic Energy of Canada, Ltd., in conjunction with the Hydro-Electric Power Commission of Ontario.

J. P. Baxter and C. N. Watson-Munro stressed the need for nationally integrated fuel cycles in Australia. Based on a number of speculative assumptions of nuclear power requirements, proportions of natural uranium and enriched reactor systems, they made some estimates of the order of requirements of Australia's needs of fertile and fissile materials during the next four decades.

The four papers on specific power reactor developments from the large British nuclear consortia, namely, "Medium Output Gas-cooled, Graphite-moderated Reactors for Australia", by A. L. Shaw (A.E.I.), "Engineering Aspects of Nuclear Power Stations employing Gas-cooled, Graphite-moderated Reactors", by K. J. Wootton (General Electric Co.), "Design of the Gas-cooled, graphite-moderated Reactor for Power Production", by R. D. Vaughan (Nuclear Power Plant Co.), and "The Hinkley Point Reactors", by Dr. H. S. Arms, C. Bottrell and P. H. N. Wolff (English Electric Co.), provided a great deal of interest.

These firms have recently given tenders in the United Kingdom for a total of about 1,400 MW. of electrical capacity, and construction work has begun on all four nuclear power stations. As one speaker put it, "The British Electrical Industry had not established a reputation as a charitable institution", and it was obvious from the papers and from the subsequent discussions that these reactor designs represented a 'down to earth' approach to the problems of providing a significant and reliable contribution to the British electricity grid. All four gave broad descriptions of current designs and discussed the areas in which improvements and reductions of cost could be achieved. Two of the papers discussed possible applications of this type of reactor to Australian conditions, and some estimates of costs—both current and futuristic—were given for reactors ranging from 60 MW. upwards.

J. M. Harrer delivered a paper entitled "Operational Data and Experience from the Experimental Boiling-water Reactor". In this paper he detailed the actual operating experience obtained over a period of twelve months with this reactor; during this period no major technical fault had developed and the claims of compactness, simplicity, safety, reliability and convenience had been substantiated.

Two papers discussing the possibilities of the reactor systems under investigation by the Australian Atomic Energy Commission Research Establishment were presented. They were: "Gas-cooled Reactors of a Mixed-fuel Moderator Type", by G. C. J. Dalton, and "Liquid-metal Fuel Reactors", by K. F. Alder. Both these reactor systems have a number of possibilities of choice of moderator, fuel diluent and coolant, but neither has yet reached the stage of a reactor experiment.

Three papers on economic questions in the development of nuclear power in Australia were presented: "The Growth in Demand for Electricity in Australia", by the Australian Department of National Development; "Atomic Power in Australia—some Economic Consideration", by the Commonwealth Bank Discussion Group; and "The Economics of Electricity Generation in Queensland and the Potential Employment of Nuclear Reactors", by R. D. Waldie.

The paper by the Department of National Development, from an examination of the relationship of growth-rates of population, real national *per capita* income, energy consumption and electrical-energy consumption, made some estimates of the growth-rates of Australian electricity demand for the next four decades.

The paper by the Commonwealth Bank examined the impact that the installation of nuclear plant of high capital cost would have on the capital demands of a rapidly developing country such as Australia. That by R. D. Waldie discussed the possible application of nuclear power to the widely separated electrical networks in the large State of Queensland and came to the conclusion that the Mt. Isa mining area offers the best possibilities.

Power Auxiliaries

This section covered research reactors, chemical processing, waste disposal and problems of power generation.

Five papers on research reactors were presented: "Canadian Research Reactors", by D. G. Hurst; "The Design and Construction of HIFAR", by W. H. Roberts; "The Control and Instrumentation of the Reactor HIFAR", by G. Page; "The First Year of Operation of DIDO", by F. W. Fenning; and "An Industrial Research Reactor", by T. E. Allibone, D. R. Chick and A. J. Salmon.

The paper by D. G. Hurst was a valuable one, particularly as Canada has had as much experience as any other country in the world in the operation of high-flux research reactors. F. W. Fenning's paper was particularly useful to Australia; except for some minor modifications described by W. H. Roberts, the Australian reactor HIFAR is a copy of DIDO, and the British experience will be invaluable in considering its operation.

The paper on the A.E.I. pool-type research reactor, presented by T. E. Allibone, evoked considerable interest as an example of an industrial firm constructing a research reactor of relatively low cost with neutron fluxes remaining close to 10^{14} neutrons per cm.^{2} per sec.

The four papers presented in the sub-section on power generation were: "Nuclear Steam-power Plant for Waterless Zones", by W. R. Wootton; "Similitude in Gas Turbines for Nuclear Power Plants", by G. G. McDonald; "Nuclear Power Reactor and Turbo-alternator Interaction under Dynamic Conditions", by H. K. Messerle and J. F. Armstrong; and "Heat Transfer in Homogeneous Gas-cooled Reactors", by G. de Vahl Davis.

The first of these was of particular interest to Australia in that it detailed a conceptual design and cost estimate of a 30-MW. (electrical) PIPPA type reactor, employing a sealed air-condenser.

Three papers on chemical processing were presented: "Chemical Reprocessing of Irradiated Fuels", by J. E. Cole; "The Future of Nuclear Fuel Processing in Australia", by G. L. Miles; and "Acid Leaching and Anodic Dissolution of Graphite-moderated Fuels", by K. R. Hyde, D. J. O'Connor and J. L. Woodhead.

J. E. Cole gave a brief survey of American practice in processing plants and gave a cost estimate of a plant capable of processing 10 tons a day of irradiated natural uranium. A number of questions were posed by Australian members of the audience on the design and economics of smaller plants. Some estimates of the likely requirements of chemical processing in Australia and of the possible kinds of plant that might be used were given by G. L. Miles.

The two papers on the treatment of waste, "Philosophy and Practice of Radioactive Waste Disposal", by R. B. Temple, and "Handling, Treatment and Disposal of Radioactive Wastes", by J. A. Lieberman, provided some lively discussion both on and off the symposium floor. It became obvious that a world appreciably powered by fission energy would need to retain control over the storage of fission products and could not allow uncontrolled disposal in the sea or elsewhere.

Basic Sciences

This section contained a wide variety of papers divisible broadly into theoretical physics, cosmic rays, reactor physics, radiation and nuclear chemistry.

The papers in theoretical physics, while of limited direct interest to the practical application of atomic energy, gave some basic scientific stimulation to the symposium. They were as follows: "Optical Treatment of Inelastic Scattering", by S. T. Butler, N. Austern and C. Pearson; "The Ground-state of the Triton; Effect of Repulsive Core Forces", by J. Blatt and G. Derrick; "The Ground-state of the Triton: Group Theoretical Classification of Wave Function", by G. Derrick and J. Blatt; and "Nuclear Forces at Very Small Distances", by S. T. Ma.

The same general remarks apply to the papers on cosmic rays, though in this case a number of papers had computing and instrumental techniques of special interest in the field of nuclear reactor research. The papers were as follows: "The Sydney Air Shower Experiment": (1) "The Experimental Apparatus", by D. D. Miller; (2) "The Determination of the Radial Distribution of Electrons and the Size Spectrum of Extensive Air Showers", by C. S. Wallace; (3) "The Zenith Angle Distribution of Air Showers", by J. Malos; (4) "The Radial Distributions of High-energy Nuclear-active Particles and of μ-Mesons in Cosmic-ray Air Showers", by J. A. Lehane.

Papers in the field of reactor physics and reactor theory were: "Some Recent Developments in the Theory of Doppler Broadening of Nuclear Resonance Regions", by J. L. Cook; "On the Second Order Terms in the Age Theory of Neutron Distribution", by L. C. Woods; "The HIFAR Oscillator", by K. P. Nicholson and A. W. Pryor; and "Neutron Diffraction on HIFAR", by T. M. Sabine. Whereas the first two of these contributed to existing reactor theory, the last two papers described specific instruments under construction for use with the Australian HIFAR reactor.

A wide range of papers was presented in the field of radiation, nuclear chemistry and chemistry, as can be seen by the following titles: "The Chemistry of Positronium", by J. W. Lee and J. H. Green; "Radiochemical Method for the Detection of Fast Neutrons", by R. Mills; "Free Radical Measurements in the Radiolysis of Liquid Hydrocarbons", by K. H. Napier and J. H. Green; "The Chemical Fate of a Radioactive Atom", by D. L. Baulch and J. F. Duncan; "Distribution Studies and Stereospecificity in Recoil Tritium-labelling of Organic Compounds", by W. G. Brown and J. L. Garnett; "The Chemical Fate of Recoiling Fission Fragments", by D. Hall; "The Solution of Lime in Liquid Calcium and its effect on the Reducing Properties of the Metal", by D. J. M. Bevan and F. D. Richardson; "The Oxidation of Particles of Uranium Dioxide", by J. S. Anderson; and "Imperfections induced in Solids by Fast-particle Irradiation", by P. G. Klemens.

These papers ranged from fundamental studies to applications outside the field of chemistry such as the paper by R. Mills on the use of the ^{56}Fe$(n,p)^{56}$Mn reaction as a threshold detector of fast neutrons.

Associated Techniques

Twenty-eight papers were presented in this section, covering a large number of topics between which there was little close relationship.

One group dealt with radioactive isotopes, the techniques of their use and their applications in various fields. A survey of the use of radioisotopes in Australia was presented by J. N. Gregory. He showed that the number of shipments of isotopes per million of the population is substantially less in Australia than in the United Kingdom, America or New Zealand. The use of isotopes is now expanding more rapidly, and with the prospect of supplies from Australia's new reactor rapid development of uses in future may be expected.

The medical uses of isotopes provided eight papers: "Evidence for a Direct Mechanism in Leukæmogenesis", by P. L. T. Ilbury; "Beta-ray Therapy with Strontium-90 Sources", by D. F. Robertson; "The Effect of Ionizing Radiation on the Synthesis of Porphyrins by the Red Blood Cells of the Domestic Fowl", by R. Tirrell; "Experimental Hæmatology using Iron-59 and Chromium-51", by I. Brading, E. P. George and R. J. Walsh; "Inaccuracy of the Colloidal Gold Method for determining Liver Blood Flow", by J. McRae, M. Playoust, R. Boden and C. R. B. Blackburn; "Localization of the Placenta using Radioisotopes", by E. P. George and D. McGrath; "Use of Radioactive Tracers in Cardiac Investigations", by E. P. George, J. Hickie, F. A. Rocke and W. A. Seldon; and "Radioiodine Studies of the Equilibrium Turnover of Thyroxine in the

Thyroid Gland", by T. H. Oddie and I. D. Thomas. All were from Australian sources and show the increasing interest in medical circles in the use of these substances.

J. Carpenter and J. S. Gladstones discussed the production of mutants induced by radiation in subterranean clover and lupins in Western Australia. Some mutants of possible commercial value have been produced and are being examined.

In a paper entitled "Analytical Chemistry in Atomic Energy", L. E. Smythe described some of the requirements for analytical work in this field. He discussed the uses of automatic coulometry, square-wave polarography, gamma-spectrometry, low-background beta-counting, infra-red spectrometry, mass-spectrometry, emission spectrography, X-ray spectrography and vacuum fusion analysis, in an analytical laboratory serving an atomic energy research establishment.

G. L. Miles and D. F. Sangster presented a detailed account of the facilities for radiochemical work at the Lucas Heights establishment of the Australian Atomic Energy Commission. They described the special facilities for working with high levels of radioactivity, the ventilation requirements and methods adopted to prevent the spread of radioactive contamination.

A comprehensive account was given by H. M. Finniston of the radioactive handling facilities at Harwell for metallurgical work with both alpha- and gamma-active materials. The paper described at some length the special problems of working with plutonium, and the ways in which complicated metallurgical procedures can be carried out while adequate protection is ensured. The problems of working with high levels of gamma-activity were also described, together with the techniques developed at Harwell for this type of work. D. Campbell Allen contributed a paper on "High Density Concrete for Radiation Shielding".

In the instrumentation group, papers were presented on "Some Temperature Effects of Geiger–Müller Tubes", by R. E. Belin; "A General Purpose Wide-range Electrometer", by C. T. Murray; and "Transistor Decade Scaling Circuits", by R. E. Aitchison.

The use of radioactive isotopes in connexion with measurement of the water content of soils was discussed by J. W. Holmes; and J. S. Watt and K. R. Lawther described the attenuation of gamma-radiation as a means of measuring the density of a slurry of tungsten powder and water moving in a pipe. B. J. J. McHugh and H. E. Booth presented a paper on the gamma-ray measurement of defects in poles and trees; cæsium-137 was used as the source of gamma-radiation and results were given on the detection of cavities, damage by white ants, and other defects, in this way.

In the chemical research field, a paper was presented on "The Diffusion of Hydrogen Sulphide Gas through Surface Films on Water" (J. G. Hawke), in which sulphur-35 was used. D. R. Llewellyn and A. L. Odell gave a paper entitled "The Use of the Isotopes Oxygen-18, Carbon-13 and Carbon-14 in the Study of the Exchange Reactions of the *tris*-Oxalato Chromium III Anion".

The only paper in the symposium on educational methods was delivered in this section. It was "Programme of Education for Nuclear Engineering and Science at the N.S.W. University of Technology", by L. C. Wood and J. H. Green. This paper described the Institute of Nuclear Engineering, which was established in this University in 1954 and which has developed during the past four years not only a substantial research programme in the University but also postgraduate courses in various branches of nuclear engineering and science. These are the only courses of this kind at present available in Australia.

MIGRATIONAL DRIFT OF BIRDS PLOTTED BY RADAR

By Dr. DAVID LACK, F.R.S.

Edward Grey Institute of Field Ornithology, Oxford

It has long been known that land birds which normally migrate north-east – south-west across the main European land mass appear on the east coast of Britain with easterly winds, but rarely under other conditions[1]. Ritchie[2] showed precisely that differences in the point at which waxwings (*Bombycilla garrulus*) arrived on the British coast on different days were explicable if their courses were the resultant between their heading in a constant direction and the wind at the time. Williamson[3] made a systematic study of the appearance of migrant land birds off their normal route, showed that such migrational drift was common, and defined the types of weather which determine it, but differed from other authors in regarding it as "essentially a down-wind movement". He also considered it as occurring primarily in night migrants. The behaviour of migrants in a cross-wind is of special interest in view of experiments showing that migrants can head in a fixed direction by day if they see the Sun[4], and by night if they can see the stars[5], and that displaced birds can 'home' apparently through a sense of geographical position which depends on the Sun[4,6].

The course of migrant birds over the sea can now be removed from the realms of inference, since the 1-MW. 10-cm. early-warning radar sets of the Royal Air Force detect small birds to ranges exceeding 60 miles (Tedd and Lack, in the press). The following information concerning directions of flight has been summarized ahead of a detailed study, in view of the continuing research by others on both drift migration and bird navigation. Personal observations of migration on a radar plan-position display in Norfolk from March 29 until April 18, 1958, were supplemented by photographs of the same display, made available by the Research Branch, Fighter Command, taken about once an hour from March 15 until April 21, 1956, and four times a minute from February 24 until April 20, 1957, a few days being missed in both years. Hence there are records from Norfolk for three successive years covering the main departure period of the land-birds wintering in England, of which the commonest are starling (*Sturnus vulgaris*), blackbird (*Turdus merula*), redwing (*T. musicus*) and chaffinch (*Fringilla coelebs*), with various other less common species, mostly passerines. These birds set off in March and April from the east coast of England over the North Sea on their way to more northerly breeding grounds.

In the period studied, the echoes from migrant birds were usually commonest soon after it was fully dark, with a subsidiary peak soon after sunrise. The volume of migration was assessed from the density of the echoes, and the directions of movement from the after-glow, which shows previous positions of each echo. At any one time, the directions were usually spread over about 45°, sometimes more, and their mean was estimated by eye to the nearest compass point, except that when two points were almost equally favoured both were cited, while when the movement was nearly due east, care was taken to see whether it was, on average, slightly north or slightly south of east. Such estimates were made twice daily, in the evening well after dark, and soon after sunrise, usually over some two hours in each period. The speed and direction of the wind were taken from the figures for Hemsby, Norfolk, in the Daily Aerological Record of the Meteorological Office, which was the nearest available point to the sea area studied.

Williamson (ref. 3, p. 185) wrote that "lack of wind is believed to be the external factor stimulating the act of migration". Table 1 shows clearly the deterrent effect of strong wind, since scarcely any large migratory movements occurred when the surface wind exceeded 15 knots at night and 10 knots by day. The direction of the wind had little influence, Table 2 showing that large migrations occurred, by night and day, with winds in every quarter. There seemed to be a slight tendency, especially by day, to favour following winds and to avoid head winds; but nearly all the large movements occurred during cross-winds, which, in the prevailing anticyclonic conditions, were usually from the north-east or south-east, that is, partly opposed to the direction of travel.

Table 1. Wind-speed and Volume of Migration

Speed at surface (knots)	After dark No. of days on which migration was: small or none	large	After dawn small or none	large
0–5	4	9	12	9
6–10	10	37	22	17
11–15	11	20	22	6
16–20	15	4	12	3
21–27	4	0	2	0
Total	44	70	70	35

Notes: (i) Radar records for most days and nights March 15–April 21, 1956, February 24–April 20, 1957, and March 29–April 18, 1958; (ii) the surface wind was recorded at Hemsby, Norfolk, at respectively 2000 and 0500 hr. in 1956 and March 1957, and at 1700 and 0800 hr. in April 1957 and 1958.

Table 2. Wind-direction and Volume of Migration

Direction of surface wind	After dark No. of occasions when migration was: small or none	large	After dawn small or none	large
Following (260°–280°)	0	2	1	5
Partly following (200°–250°, 290°–340°)	5	11	4	7
Cross (170°–190°, 350°–010°)	5	18	7	7
Partly opposed (020°–070°, 110°–160°)	8	27	7	7
Opposed (080°–100°)	3	3	4	2

Notes: (i) Winds recorded at Hemsby, as noted in Table 1; (ii) all occasions were omitted in which the wind was less than 6 knots, and also those with a small migration in which the wind was more than 15 knots by night and more than 10 knots by day.

Table 3. Direction of Wind at 900 m. and Direction of Migration

Mean direction of bird migration in North Sea	No. of occasions on which direction from which wind blew at 900 m. at Hemsby was: East 080–100	Southerly 110–160	170–190	200–250	West 260–280	Northerly 290–340	350–010	020–070
				After dark				
N.N.E.		1						
N.E.	1	6	6	3				
N.E.–E.N.E.		3	3	1	1			
E.N.E.	2	5	2	6	4	1		
E.N.E.–E.					6	1	1	1
E.		1			2	1	4	4
E.–E.S.E.						1	3	
E.S.E.				1		3	5	3
E.S.E.–S.E.								1
S.E.						1	1	7
				After dawn				
N.E.		6	2	2				
N.E.–E.N.E.		1	2	1				
E.N.E.		2	2	4	1			
E.N.E.–E.			1	2	2	2		
E.	1	1	1		3	6	1	1
E.–E.S.E.				1		3	1	1
E.S.E.		1				2	2	3
E.S.E.–S.E.							1	3
S.E.						1	1	2
S.S.E.								2

Note: Directions were usually spread over about 45°, sometimes more. The mean was estimated by eye, whenever possible to one of the main compass directions. Two directions are joined, for example, N.E.–E.N.E., when there were about an equal number of each on the occasion concerned.

The evidence from radar height-finders and other sources indicates that most of the migrants were travelling between 2,000 and 4,000 ft. above sea-level; hence for analysing the influence of the wind on the directions taken, the figures for the wind at 900 m. were used, and these, in fact, gave smoother results than those for the wind at the surface or at 1,500 m. Using only the direction of the wind (wind-strength will be analysed later) Table 3 suffices to show that the course taken, both by night and by day, is the resultant between a more or less constant heading (probably slightly north of east) and the wind at the time. On almost every occasion when the wind (at Hemsby) had a southerly component, the migrants over the sea travelled on a course north of east, and on almost every occasion when the wind at Hemsby had a northerly component, they travelled on a course south of east. Further, nearly all the few apparent exceptions to this statement in Table 3 are readily explicable, since they occurred when there was a marked shift in the direction of the wind at Hemsby, either in the course of the period in question, or between the surface and 900 m.; while in a few cases when the birds travelled a little north of east with a northerly wind, the wind was very light. Hence, these findings fully support Ritchie's view that the course taken by drifted migrants is the resultant between the heading of the birds and the wind, and they also confirm that migrational drift is exceedingly common, since it occurred almost every day and every night, and there was no difference between the day and the night in its frequency or nature.

This evidence indicates that, when over the sea, the migrants maintained a constant heading by means of their sense of direction (based on the position of the Sun or the stars), but that they did not at all correct for wind drift by that more mysterious capacity by which they 'home'. Their course from

Norfolk varied between north-east and south-east, sometimes on successive nights, so that, according to the night on which they happened to travel, the migrants might make their landfall anywhere between mid-Denmark and Belgium, some 400 miles apart. It is at this juncture, presumably, that their sense of geographical position comes into play. That birds possess such a capacity is shown not only by homing experiments[4,6] but also by the fact that various drifted migrants trapped and ringed in Britain have later been recovered in their normal Continental wintering or breeding grounds well to the east, and Williamson has rightly stressed the importance of such re-directed movements. Indeed, it may be claimed that the homing sense, now demonstrated in many species of birds, is primarily an adaptation to counteract drift, which the present observations show to be a normal accompaniment of migration.

The observations in Table 3 refer to directions over the sea. Many fewer directions were observed over the land in Norfolk, but these followed the same general trends, the birds travelling south of east with northerly winds and north of east with southerly winds. Hence migrational drift also occurs over the land, though if the birds fly lower when over the land than over the sea, their drift will be smaller, since the wind is normally weaker nearer the ground. These remarks, it should be added, refer only to those migrants flying high enough over the land to be detected by radar, and not to those flying low by day, which may follow the coast or other 'guiding lines'.

While, as shown here, migrational drift is regular in fine or moderately fine weather, Williamson and others have found that drifted migrants land in large numbers at the British east-coast bird observatories primarily when they must have met wholly overcast conditions during the course of their journey. Under such conditions, birds can no longer see to navigate by the Sun or stars. Moreover, as is well known, they do not normally set off on their migrations in such weather, hence the spring departure from Norfolk normally provides unsuitable conditions for studying what happens. However, in clear weather on the afternoon of April 17, 1958, many redwings and other species took off rather north of east, and soon after dark, mist and rain became general. Rain echoes came to obscure most of the plan-position display, but one gap remained well out to sea, and here, between 2030 and 2130 hr., I had quite unusual difficulty in establishing the directions of the birds from the afterglow of the echoes. In one period, for example, there seemed to be twenty-one directions scattered fairly evenly between north-north-east and south-east, and eleven others between south-south-west and north-north-west; but the afterglow was normally short, and soon afterwards the directions often seemed to have changed. Yet only three hours earlier, in fine weather, there were many sustained tracks in a nearly constant direction north of east, and the same applied once more when the rain cleared off in the early morning. Presumably, during the period of fully overcast conditions, the birds could not maintain their heading, and flew around irregularly with repeated changes of direction.

It is hoped to study such conditions more fully later; but provisionally the radar evidence suggests that migrants meeting fully overcast skies over the sea fly around irregularly and indecisively, in which case their eventual direction will be that of the wind at the time. Further, they are likely under these conditions to become extremely tired, and so will tend to alight at the first land encountered. With normal drift in fine weather, on the other hand, migrants reaching the coast seem usually to proceed some way farther before settling, and so are not concentrated at the point of arrival. Hence it is primarily when migrants meet overcast conditions that they later appear in large numbers at the British bird observatories.

I am extremely grateful to the Air Ministry and to the Research Branch, Fighter Command, for allowing me full facilities for this work, and to Mr. W. G. Harper, of the Meteorological Office, East Hill, who is also working on birds and radar[7], for most helpful discussions. The pioneer work in this field of E. Sutter[8] was an invaluable spur.

OBITUARIES

Prof. C. H. Desch, F.R.S.

No one could come in contact with Cecil Henry Desch, who died on June 19 at the age of eighty-four, without being influenced by his astounding knowledge and complete sincerity. Educated at Birkbeck School, Finsbury Technical College and University College, London, as a chemist, he then went to Würzburg, where he obtained his doctorate.

After being connected with the brewery and cement industries for a short time, he joined the Metallurgical Department of King's College, London, in 1902, and it was during this time that much of the work on his book on "Metallography" was done. In the preparation of this volume he was greatly indebted to Mrs. Desch for the preparation of the beautiful microsections with which it was illustrated. The influence of this book on English metallurgy was immense. In many ways it broke new ground, and it may be that this represents his greatest influence on metallurgical science, in any event in Great Britain.

In 1909, Desch was appointed to the Graham Young lectureship in metallurgical chemistry in the University of Glasgow, remaining there until the end of the First World War, when he was appointed to the chair of metallurgy at the Royal Technical College in that city. His tenure of this chair was short (1918–20), and on the retirement of Arnold he succeeded him in the chair of metallurgy in the University of Sheffield. His twelve years in this chair saw immense changes and the beginning of the modernization which was inevitable if its reputation was to be maintained, and it was during this time that I knew him best. It was not an easy job to follow Arnold and to make the changes in the existing course which Desch saw to be essential, and those in closest scientific contact with him must have wondered whether this post was really congenial.

In 1932 he resigned his chair, to follow Rosenhain as superintendent of the Department of Metallurgy at the National Physical Laboratory, remaining there until his retirement, in 1939.

Desch's next appointment must have surprised most of those who knew him, for in the November of that year he was appointed, by Securities Management Trust Ltd., to the board of Richard Thomas and Co., Ltd. In 1943 he resigned, on appointment as chief scientific adviser to the Whitehead Iron and Steel Co., Ltd. This complete change from academic to industrial life, however, seemed to give him real satisfaction. It was not his first experience of industry, and the possibility of applying his wide knowledge to the industrial needs of the country at a critical time was compatible with his life-long interest in sociological problems. These had, I believe, at an earlier date led him to become somewhat republican in his political thought, though this changed later, when he again became (mildly) royalist.

Desch's quite outstandingly successful book on metallography was followed, in 1914, by one on "Intermetallic Compounds". Despite all the changes which have taken place in the intervening years, this is still a book which may be read with profit, and was, when first published, of the greatest interest. In addition, and largely as a result of the visit paid, in 1931, to the United States of America, where he was the George Fisher Baker Lecturer at Cornell University, he published one of the earlier books on the solid state, the "Chemistry of Solids", largely based on the lectures which he gave there.

Over a number of years he was greatly interested in early metallurgy, as a result of which a number of reports were submitted to the British Association on the source of metals used by the Sumerians and other ancient peoples.

Elected to the Royal Society in 1923, he was president of the Faraday Society during 1926–28 and received the Bessemer Gold Medal from the Iron and Steel Institute and the Platinum Medal of the Institute of Metals, both the highest distinctions which these Institutes have it in their power to confer.

It was as a teacher, however, that Desch probably reached his highest level. He was an excellent lecturer, and the width of his knowledge enabled him to weave together facts and ideas obtained from an almost unique variety of sources. His mind was not strikingly original and his researches in metallurgy did not make any very lasting mark on its development.

This account of his scientific life and the important posts which he held gives, however, an inadequate description of the man himself. His complete sincerity of thought and his interest in human needs in general have already been mentioned. Among his relaxations was his interest in geology, a fact which led to his very good Sorby Lecture, delivered in 1921. His somewhat shambling gait was characteristic, but it carried him over many miles of rough country.

F. C. THOMPSON

Mr. H. E. Balch

MR. H. E. BALCH, honorary curator of the museum at Wells, Somerset, for sixty-one years, died on May 27 at the advanced age of eighty-eight.

Starting life as a messenger in the Post Office and finally rising to the position of head postmaster at Wells, he devoted the whole of his leisure time to the exploration of the Mendip Hills, and this in spite of the long hours of duty involved in his work. In 1893 he started a museum of his own material in the West Cloister of Wells Cathedral. An ardent collector himself, he soon persuaded others to give, and in 1928, through the generosity and interest of Mr. William Wyndham, the Museum was moved to a large house in the Cathedral Green. He was made chairman of the Trustees for life and honorary curator, a position he held until his retirement in 1954.

Balch had many publications to his credit, his major work undoubtedly being the large monograph on the excavations at Wookey Hole. He was awarded the honorary degree of master of arts in the University of Bristol in 1925 and was presented with the freedom of the City of Wells in 1944. He will be remembered with affection by many for his devotion and zeal to the elucidation of the problems of Mendip and for the amassing of such valuable collections which now and for the future will form the basis of the important museum at Wells. F. S. WALLIS

NEWS and VIEWS

Ministry of Supply Electronics Research and Development (Telecommunications): Mr. R. G. Friend

MR. R. G. FRIEND, who has been appointed director of electronics research and development (telecommunications) in the Ministry of Supply, read physics at Queens' College, Cambridge, where he was a Foundation Scholar and took first- and second-class honours in the two parts of the Natural Science Tripos. He then joined the Research Department, Woolwich Arsenal, where for some years he was engaged on research on X-ray and magnetic methods of material testing. In 1935, he transferred to the Air Defence Experimental Establishment for acoustical research with particular reference to the development of a new sound locator using electrical delay lines. Early in 1939, Mr. Friend was selected to move to Bawdsey to join a small team working with Sir Robert Watson-Watt on the application of the new radar techniques to Army problems. On the outbreak of war, this team moved to Christchurch, where it expanded and ultimately became the Radar Research and Development Establishment. Throughout the Second World War, Mr. Friend continued in this work and was responsible for many contributions in the fields of radar fire control for anti-aircraft guns and of counter-measures to radar jamming. He was for some years in charge of the Fire Control Group and later the Basic Techniques Research Group. In 1954 he moved to the headquarters of the Ministry of Supply on appointment as assistant director of electronics research and development. In this post, and later as acting director, he has been responsible for the research and development aspects of all ground radar for both the R.A.F. and Army applications.

Armament Research and Development Establishment : Dr. D. H. Black, C.M.G.

Dr. D. H. Black, who has been appointed director of the Armament Research and Development Establishment of the Ministry of Supply, in succession to Mr. E. McEwen, was born in 1899 in New Zealand, where he received his early education, taking first-class honours in physics at Canterbury. He came to Britain to work under the late Lord Rutherford in the Cavendish Laboratory, Cambridge, in 1923, gaining his Ph.D. in 1925. Dr. Black spent some fourteen years in industrial research with Standard Telephones and Cables, ultimately as head of the Valve Laboratory, before joining the Government service in September 1939, when he was appointed superintendent of the then Air Defence Experimental Establishment. In 1943, he was seconded to the Admiralty for special liaison duties in the United States, mainly concerned with new valve and electronic developments for radar and communications. He returned in 1945 as superintendent in charge of research at the now renamed Radar Research and Development Establishment, and in 1947 he moved to the headquarters of the Ministry of Supply, becoming director of electronics research and development in 1949. In 1953, Dr. Black was appointed head of the U.K. Ministry of Supply mission in Australia. During his three years in this post, the interests of the Ministry in Australia expanded considerably with the development of the guided weapon and atomic trials at Woomera and Maralinga. For his work in this post Dr. Black was appointed C.M.G. On returning to England in 1956, Dr. Black was appointed director-general of electronics research and development at the Ministry of Supply headquarters. Widely known in electronics and scientific circles, his appointment as head of the Armament Research and Development Establishment is indication of the increasing importance of electronics in all branches of armaments, as well as of his own personal and scientific strength.

British Scientific Instrument Research Association : Mr. R. J. Bracey

Mr. R. J. Bracey, head of the Optical Department of the British Scientific Instrument Research Association, will retire on July 31, after thirty-three years of service with the Association—and forty years of service to the optical industry. While still a boy, Bracey developed a deep interest in mathematics and a desire to apply his mathematical gifts to optical design, and after working for six years for a firm of shipbrokers and in a bank, he joined the firm of R. and J. Beck, the microscope makers. There he worked for the next seven years, in the shops and as a designer, until 1924, when Sir Herbert Jackson, then director of the British Scientific Instrument Research Association, invited Bracey to join the staff. Bracey's work during the next thirty-three years is reflected in the thirty-six research reports which bear his name or signature, twenty-four of them concerned specifically with optical design. Microscope objectives, including pioneering systems for ultra-violet microscopy; optical systems for telescopes; illuminators; focometers for spectacle lenses; systems of ray tracing; lens and mirror systems; interferometers; collimators; the optics of clinical thermometers; the examination of bearing jewels—Bracey's field has been wide. The $f/0{\cdot}36$ object-glass designed by Bracey for stellar spectroscopy at the Mount Wilson Observatory is one of his most important designs. Bracey's long service to the industry will not end with his retirement. It may be, indeed, that one of his greatest services is still to come, because the monograph on optical design which he is now writing and will complete in retirement may well prove to be an outstanding contribution to the literature of the subject. His services as a consultant will still be available to the Research Association.

Mount Wilson and Palomar Observatories : Dr. W. Baade

Dr. Walter Baade, who has been a member of the staff of the Mount Wilson and Palomar Observatories for twenty-seven years, is to retire. Dr. Baade, who was born at Schroettinghausen, in Germany, received his Ph.D. in 1919 at Göttingen and the same year was appointed to the staff of the Hamburg Observatory, where he remained until he received his appointment to the staff of Mount Wilson in 1931. Dr. Baade is noted for his discovery that two entirely different types of stars (Populations I and II) exist. This led to his recalibration of Cepheid variable stars in the Andromeda nebula, and his correction of the cosmic-distance scale. His work, which was reported at the International Astronomical Union meeting in September 1952, indicated that all objects beyond the Milky Way are about twice as distant as had previously been supposed. He has also collaborated with Dr. Rudolph Minkowski in the identification of celestial radio sources with visual objects, and in the physical interpretation of the nature of these sources. In 1954, Dr. Baade was awarded the Gold Medal of the Royal Astronomical Society, "for his observational work on galactic and extragalactic objects".

The Warren Spring Laboratory

The new Department of Scientific and Industrial Research Laboratory, now being built at Stevenage, will be called the Warren Spring Laboratory. The name is taken from a lane that used to run across the site on which the laboratory is being built. The Council for Scientific and Industrial Research has expressed the view that the Warren Spring Laboratory should be a versatile station, free to do work on any subject which becomes important for the nation and which cannot be fitted into the programme of another research body. It has already been decided that work will be carried out on air pollution; on the synthesis of oil and chemicals from carbon monoxide and hydrogen; and on mineral processing. The new station will, in addition, be free to take up any research requiring staff and facilities of the type that are being provided. Mr. S. H. Clarke, director of fire research, Department of Scientific and Industrial Research, has been appointed director of the Warren Spring Laboratory.

International Inspection of Nuclear Power Plants

A question was asked in the House of Commons on July 10 as to whether Britain would make it a condition of supplying civilian nuclear power plants to Brazil, Germany, Spain and other countries that continuous inspection should be undertaken by the International Atomic Energy Agency. The Prime Minister replied, pointing out that the Agency has not yet worked out methods for implementing the inspection and other safeguard provisions in its governing statute. All that can be done is to specify in the contracts the right of supervision by the appropriate international agency. Contract orders placed this year, which will not operate before 1961 or 1962, will enable the Government to insist upon whatever methods of inspection seem proper and desirable. Mr. Macmillan also pointed out that the Agency is a board of twenty-three governors from as many countries with somewhat different approaches to this matter and that it may be difficult to get such a board to agree to adopt a particular form of technical operation. If it cannot be done in one particular way there may be some other agency or method for securing effective control; we have perhaps three or four years in which to work out the best method.

Nuclear Reactor for Winfrith Heath

In a written answer in the House of Commons on July 8, the Prime Minister said that it has been decided on technical grounds that the homogeneous aqueous reactor system planned for Winfrith Heath is not at present suitable for a major research and development effort, either by the Atomic Energy Authority alone or as a joint programme under the European Nuclear Energy Agency. Discussions are now in progress in the Agency about a joint research programme on the high-temperature gas-cooled reactor, a system which holds considerable promise for generating power but which has not yet been investigated in detail. This would include the construction of an experimental reactor in the United Kingdom, and Mr. Macmillan hoped that a satisfactory agreement will be concluded in the next few months. On the same day it was stated that the British Government contributes about one-quarter to the total budget for 1958 of £4,660,000 of the European Organization for Nuclear Research.

Research in the Aircraft Industry

The debate on the aircraft industry, which was opened by Viscount de L'Isle in the House of Lords on July 16, is of interest for the consistent emphasis laid on the importance of research by almost all speakers. Lord de L'Isle said that the industry is one of three or four in Britain in which it is vital to the national economy that it should gain and maintain a leading position in the world, and added that in this industry the demand to plough back money in research and development is the most insistent; he put the necessary figure at 20–30 per cent of turnover. Lord Ogmore, who asked again for an independent inquiry into the structure and situation of the industry, questioned whether it was possible to provide finance for research and development necessary for supersonic airliners from non-military sources alone, and said that about six of the 200 firms in the industry are responsible for 80–90 per cent of the output. The Earl of Swinton, urging that it is the duty of the Government to have a definite policy of development and to make this plain to the industry, argued firmly that we cannot afford to skimp expenditure on research, while Lord Adrian, pointing out that the aircraft industry is in the forefront of technological progress, said that there is scarcely any field of technical advance which did not receive an immense stimulus from war-time developments in aircraft. Instancing radio, metallurgy, engine design, electronic control and almost every kind of fine engineering, he said that the problem is whether we could afford to lose the technology which would go into the planes no longer required for defence, since it would be applied to machines and have just as much influence on industrial development as many developments in nuclear energy. The value of the applied research required for building a full-scale machine was not easily over-rated, and Lord Adrian believed that an important case can be made for Government sponsorship of the design and construction of some advanced machines. Viscount Caldecote strongly supported Lord Adrian's plea, pointing out also the vital need for continuity in research and suggesting allocation of finance for research and development over a five-year period: research cannot be stopped and restarted. He also supported Lord Weeks in a plea for clear guidance to the industry from the Government in policy. Lord Pakenham advocated the formation of a board in the Ministry of Supply, including industrial representation from outside the aircraft industry. Lord Mancroft, in reply, agreed as to the vital importance of research, but added little to the Minister of Supply's statement in the House of Commons on May 22 in reaffirming that the Government would continue to support the basic research necessary for the industry to survive, both in Government establishments and in industry, and that this would include the construction of research aircraft.

The Clean Air Act, 1956

As from June 1, 1958, the Clean Air Act, 1956, much of which has been in operation since the beginning of 1957, is fully in force, and it will be an offence punishable by fine to emit 'dark smoke' (defined as as dark or darker than shade 2 on the Ringelmann Chart) from any chimney in England and Wales. The ban on dark smoke applies to all buildings, and to railway engines and ships, but it will chiefly affect industrial and commercial premises, and the Minister of Housing and Local Government has issued a Memorandum on the Industrial Provisions (pp. 20. London: H.M. Stationery Office, 1958. 1*s*. net) to assist local authorities in administering these provisions of the Act. It directs attention to certain allowable defences and emphasizes the economies in fuel which can result from measures to reduce smoke. Surveys of Lancashire boilers carried out in 1956 by the National Industrial Fuel Efficiency Service indicate that adoption of measures to improve fuel efficiency on the 18,000 boilers in regular use should offer a saving of 3 million tons of coal a year against a capital expenditure of not more than £14 million. The Act also requires steps to be taken to reduce the emission of grit and dust from industrial chimneys. New furnaces installed after June 1 for burning pulverized fuel or more than 1 ton per hour of other solid fuel must be fitted with grit- and dust-arresting plant approved by the local authority.

European Agricultural Aviation Centre

A European Agricultural Aviation Centre has been set up under the auspices of the European Productivity Agency of the Organization for European Economic Co-operation, with headquarters at The Hague. Its task is to promote co-operation and efficiency in agricultural aviation in Europe and to act as a co-ordinating centre for the dissemination of information and the stimulation of research and development in this field. The need for such a centre has long been apparent in agricultural, industrial and scientific circles. The special type of aircraft used in the application of crop-protection chemicals, fertilizers and seeds are expensive to construct and operate, and to pay their way must be employed to the full during the short season when they are required. This should be possible by operational pooling of the 200 aircraft available and by their use on a south-to-north basis following the seasonal advance. By promoting co-operation on a European scale, these aircraft can be used more efficiently and offer an invaluable adjunct to normal farming methods. During the first two years of its existence, the European Agricultural Aviation Centre will be supported financially partly by the European Productivity Agency and partly by the Dutch Ministry of Agriculture, Fisheries and Food; liaison officers in the participating countries (Denmark, France, Germany, Italy, the Netherlands, Sweden, the United Kingdom, Spain and Yugoslavia) will co-operate in its work. At the end of this period it is anticipated that the agricultural and industrial concerns which benefit from its work will contribute to the Centre's continuation and development, together with interested governments.

An Existing Cœlacanth, *Latimeria chalumnae*, in the British Museum (Natural History)

The first specimen of an existing cœlacanth fish, *Latimeria chalumnae*, to reach Britain has been placed on view in the Fish Gallery of the British Museum (Natural History), London. It was brought over by Prof. Jacques Millot, director of the Institut Scientifique de Madagascar, together with a plaster cast of an earlier specimen, and presented to Sir Gavin de Beer, director of the Museum, to mark the occasion of the Fifteenth International Congress of Zoology. Cœlacanth fishes have a particularly long and interesting history. They are found as fossils in rocks laid down during the Devonian period, indicating that they were in existence some three hundred million years ago, and closely related fossils have been found in many parts of the world, including Europe, throughout the succeeding two hundred and thirty million years. None was known in any formation more recent than the Cretaceous, and cœlacanths were thought to have been extinct for the past seventy million years. In 1938, a large steel-blue fish with many extraordinary features, caught off the coast of East Africa, was identified by Prof. J. L. B. Smith, of Rhodes University, Grahamstown, as a living member of this ancient group. It was named *Latimeria chalumnae*, and since then about a dozen more specimens of *Latimeria* have been found.

Advertising

Lord Heyworth's address at the annual general meeting in London of Unilever, Ltd., on April 24, has been reproduced for private circulation under the title "Advertising" (pp. 17. London: Unilever, Ltd., 1958). In 1957, Unilever spent on advertising £83 million, nearly half in North America alone, and Lord Heyworth defends advertising as a prerequisite to real democratic freedom of choice and an aid to 'progress'; he also suggests that it promotes both the development of new products and their establishment on a more predictable basis. Particularly in the field of what economists term 'consumer durables', such as motor-cars, television sets and refrigerators, but also with soap powder and margarine, Lord Heyworth thinks that advertising brings savings to set against its cost. He refers briefly to the most recent means of advertising—television—and claims that in Britain it has provided an efficient means of communicating with consumers which has been welcome. Finally, Lord Heyworth emphasizes the need for market research, to enable the producer not only to give the customer what she wants but also to find out what she will want in the future.

National Parks in South Africa

The Board of Trustees of the National Parks of the Union of South Africa has under its care five parks: the Kruger (7,340 sq. miles), Kalahari Gemsbok (8,050 sq. miles), Addo Elephant (26·5 sq. miles), Mountain Zebra (5·8 sq. miles) and Bonithole (2·8 sq. miles). Opportunities for research in these vast spaces are tremendous and much fruitful work has already been accomplished. To allow its investigations to become as widely known as possible, the Board of Trustees has launched a new journal devoted entirely to descriptions of work done in the National Parks (*Koedoe*, No. 1, 1958. (Journal for Scientific Research in the National Parks of the Union of South Africa.) Pp. 200. Published annually. Pretoria: National Parks Board of Trustees, 1958). Most of the articles are in English, while the few in Afrikaans have English summaries. Among the outstanding articles is a culicine mosquito survey of the Kruger National Park, some aspects of animal ecology in the Kalahari, and ancient and recent observations on hyænas. The journal has got off to a good start and deserves encouragement.

New Psychological Periodicals

Vita Humana (International Journal of Human Development. Vol. 1, No. 2, 1958. Pp. 65–128. Published quarterly. Basel and New York: S. Karger, 1958. 38.50 Swiss francs for 1 volume consisting of 4 numbers) is a new journal of human biology. It will be concerned principally with the psychological aspects of development, having particular regard to the maturation of behaviour in childhood and to changes in human performance with advancing age. The current part (1, No. 2) contains a report from Birmingham on the psychological status of deprived children and a discussion on the methodology of 'longitudinal research' in the study of human behaviour. The journal is edited by Prof. H. Thomae, of Erlangen, with an international advisory board.

Confinia Psychiatrica (Vol. 1, No. 2, 1958. Pp. 69–132. Published quarterly. Basel and New York: S. Karger, 1958. 38.50 Swiss francs for 1 volume consisting of 4 numbers) is devoted to the borderlands of psychiatry. It will be concerned less with clinical topics than with scientific and philosophical issues having relevance to psychological medicine. Summaries of papers are given in English, French and German. The editors are H. Heimann and Th. Spoerri.

Physical Review Letters

It was announced in the April issues of the *Physical Review* that beginning with the issue dated July 1 the *Physical Review* will no longer carry the feature 'Letters to the Editor', but that the 'Letters' will be published separately in a supplementary fortnightly journal to be called *Physical Review Letters* (1, No. 1, July 1, 1958. Pp. ii+48). The new journal, which includes abstracts of future *Physical Review* articles, will initially be sent free of charge to all subscribers of the *Physical Review*, though from January 1959 onwards a subscription will be charged (to members of the American Physical Society in the United States and Canada, 5 dollars ; elsewhere, 6 dollars ; to non-members in the United States and Canada, 10 dollars ; elsewhere, 11 dollars. Subscriptions should be addressed to the American Institute of Physics, 335 East 45th Street, New York 17, New York). The object of the new journal is to obtain speedy publication and by the use of offset printing to reduce the time between receipt and publication of the letters to two to three weeks. On the average, about fifteen letters will be accepted for each issue and only if they contain important new discoveries or cover topics of high current interest in rapidly changing fields of research.

Government Museum, Madras

THE Administration Report of the Government Museum, Madras, for 1955–56 (pp. vi+60. Madras: Government Printer, 1957), states that following an intensive campaign in publicity, including posters in railway stations all over India, the number of visitors shows a marked increase of 35 per cent over the previous year. Attention has been given to courses in museum technique, and these were held in the natural sciences, archæology, anthropology and chemical conservation. Much routine work has been accomplished in each Department and re-labelling has proceeded in English and Tamil. The Museum has also been very active in its Conservation and Photographic Departments. This work includes the treatment of ancient bronze images by electrolytic methods, and lead coins with dilute acetic acid under control.

Nutritional Requirements

A NEW Food and Agriculture Organization publication (Nutritional Studies, No. 16: Protein Requirements—Report of the F.A.O. Committee, Rome, Italy, October 24–31, 1955. Pp. v+52. Rome: Food and Agriculture Organization of the United Nations; London: H.M. Stationery Office, 1957. 3*s*. 9*d*. net; 0·75 dollars) deals with protein requirements in human nutrition. The report follows two others (No. 5, 1950; and No. 15, 1957), which considered calorie requirements. An attempt is made to assess the needs in terms of a reference high-quality protein (that from milk, eggs or meat). The report briefly discusses basic concepts such as nitrogen equilibrium, essential amino-acids and biological value. The estimated average minimum requirements, in terms of high-quality protein, range from 2·0 gm./kgm. body-weight in infants to 0·35 gm./kgm. for adults. To allow for individual variations in requirement, an increment of 50 per cent is recommended, with a further allowance because the dietary protein will usually be inferior to the reference protein. A section on the practical approach deals with ways of supplementing diets poor in protein and with ways of calculating allowances. An appendix outlines suggestions for further research.

Japanese Laminariaceae

ALGOLOGISTS may be interested to know that the classic monograph "On the Laminariaceae of Hokkaido" (1902), by the late Dr. K. Miyabe, is now available in an English translation (*J. Sapporo Agric. Coll.*, 1, pp. 50, with 29 plates; 1957). The monograph contains a general classification of the family and detailed descriptions of genera and species, with extensive notes on habitat and uses. The beautiful and interesting illustrations, which are a feature of the monograph, are well reproduced.

New Development of Philips Gas Refrigerating Machine

AN addition to the range of the Philips gas refrigerating machine (see *Nature*, 180, 892; 1957) is announced by the distributors, Research and Control Instruments, Ltd. This new machine (the *PW* 7050) incorporates a nitrogen-separation column, by which means air can be liquefied and separated at atmospheric pressure to produce four litres of liquid nitrogen per hour. Continuous operation is possible for a period of one week before de-frosting becomes necessary. Special features of the *PW* 7050 are: fully automatic operation without the need of supervision; small dimensions compared with conventional equipment—the column stands approximately 6 ft. high; risk of contamination is negligible because the air is cooled at atmospheric pressure in a single stage and does not pass through any moving parts. Further information can be obtained from Research and Control Instruments, Ltd., Instrument House, 207 King's Cross Road, London, W.C.1.

Carlsberg-Wellcome Travelling Research Fellowships

THE Carlsberg Foundation (Copenhagen) and the Wellcome Trust (London) announce a second series of awards of the Carlsberg-Wellcome Travelling Research Fellowships which they jointly instituted in 1957 (see *Nature*, 181, 743; 1958). The successful candidates for the academic year 1958–59 are Dr. S. E. Jensen and Dr. D. A. T. Dick. Dr. Jensen, of the Kommunehospitalet, Aarhus, and University of Aarhus, Denmark, will work in Prof. Russell Fraser's Department at the Postgraduate Medical School of London on the factors affecting serum lipoids in man, and Dr. Dick, from the Department of Human Anatomy, University of Oxford, will work with Prof. H. Holter at the Carlsberg Laboratory on the osmotic properties of living cells.

National Research Council of Canada: Scholarships

THE National Research Council of Canada has granted 302 scholarships for the academic year 1958–59, with a total value of 414,700 dollars. These scholarships include ninety-four bursaries worth 1,000 dollars each and 145 studentships worth 1,200 dollars each, all of which are tenable in Canada. Special scholarships awarded for study abroad include forty-six awards worth 2,000 dollars each. These special scholarships are to be held in the following countries: twenty-one in the United Kingdom, twenty-two in the United States, and one each in France, Sweden and Switzerland. Seventeen postdoctorate overseas fellowships, valued at 3,500 dollars for married and 2,700 dollars for single fellows, have been granted for work in the following countries: eleven in the United Kingdom, and one each in Belgium, France, Germany, Italy, Sweden and Switzerland.

Granada Television Research Fellowship

GRANADA TV NETWORK, LTD., has offered a sum of not less than £30,000 to the University of Leeds to be spent over a period of five years in supporting a Granada Television Research Fellowship and in providing the necessary ancillary staff. The offer includes further financial help and the possibility of renewal for a period if these should prove desirable. The purpose of the Fellowship will be to undertake research into the public impact of television over as wide an area of inquiry as practicable—social, æsthetic, political and commercial—and will cover television transmission from any sources in the British Isles. This study is one which will be of interest to a number of departments in the University, including social studies, economics, psychology, philosophy and history.

"Structure of Brain Ganglioside"

Dr. Samuel Bogoch, director of the Neurochemical Research Laboratory and senior psychiatrist, Massachusetts Mental Health Center (Harvard Medical School), has written in connexion with the note under this title published in *Nature*, February 1, p. 314. He states that "his communication under this title published earlier in *Nature* (July 27, 1957, p. 197) referred to previous related work by him (1953–55) from his Harvard doctoral thesis, and described recent work by him done at the Neurochemical Research Laboratory, Massachusetts Mental Health Center, in 1956 and 1957. The latter was supported by grants to Dr. S. Bogoch (principal investigator) from the National Institute of Mental Health and the National Institute of Neurological Diseases and Blindness (U.S.) (Grant No. *M*–1330: grant period June 1, 1956, to May 31, 1957; and Grant No. *B*-1221: grant period November 1, 1956, to October 31, 1957), and not by the American Cancer Society". The Editors of *Nature* have printed these statements from Dr. J. Folch-Pi and Dr. S. Bogoch, but they cannot give further space to the matter.

The Night Sky in August

New moon occurs on Aug. 15d. 03h. 33m. U.T., and full moon on Aug. 29d. 05h. 53m. The following conjunctions with the Moon take place: Aug. 7d. 10h., Mars 1° S.; Aug. 19d. 15h., Jupiter 0·9° N.; Aug. 23d. 08h., Saturn 3° S. In addition to these conjunctions with the Moon, Venus is in conjunction with Pollux on Aug. 10d. 23h., Venus being 6·7° S. Mercury is too close to the Sun for observation. Venus is a morning star, visible low in the south-east before sunrise. It rises at 2h. 10m., 2h. 40m. and 3h. 25m. on August 1, 15 and 31, respectively; its stellar magnitude is −3·3. During the month its distance from the Earth increases from 137 to 149 million miles and the visible portion of the apparent disk from 0·890 to 0·947. Mars rises at 22h. 45m., 22h. 05m. and 21h. 20m. at the beginning, middle and end of the month, respectively. Its stellar magnitude increases during the month from −0·1 to −0·5, its distance from the Earth decreasing from 86 to 70 million miles. Mars continues to move eastwards among the stars, being in Aries throughout the month. Jupiter sets at 22h. 10m., 21h. 20m. and 20h. 20m. on August 1, 15 and 31, respectively; it is near Spica. Conditions for the observation of Jupiter are becoming unfavourable; the planet may be visible low in the west after sunset. Its stellar magnitude is −1·4. Saturn sets at 0h. 35m., 23h. 40m. and 22h. 35m. at the beginning, middle and end of the month, respectively; it is near θ Ophiuchi. It has a stellar magnitude of +0·6 and a distance of 890 million miles from the Earth on August 15. There is one occultation of a star brighter than magnitude 6 visible at Greenwich: Aug. 5d. 00h. 40·5m., 147 B. Psc. (re-appearance). The Perseid meteors are active during the first fortnight of the month, maximum activity being on August 11. Conditions are favourable, the radiant being near R.A. 3h. 04m., Dec. +58°.

Announcements

Miss I. Phyllis Barclay-Smith, secretary of the International Committee for Bird Preservation, has been awarded the Silver Medal of the V. von Heidenstams Foundation in Sweden, for her work on behalf of the preservation of migratory birds. The Medal, which is rarely awarded to foreigners, was presented to Miss Barclay-Smith at Helsinki during the recent Conference there of the International Committee for Bird Preservation.

Mr. F. L. Barrett, of the Bleachers' Association Research Laboratories, Bromley Cross, has been made an honorary member of the Textile Institute.

The third International Neurochemical Symposium, on "The Chemical Pathology of the Nervous System", will be held at Strasbourg during August 25–29. Further information can be obtained from Dr. D. Richter, M.R.C. Neuropsychiatric Research Unit, Whitchurch Hospital, Cardiff.

A meeting on "The Biosynthesis of Phenolic Compounds in Plants", organized by the Plant Phenolics Group, will be held in Cambridge, on September 19, under the chairmanship of Sir Robert Robinson. Further information can be obtained from Dr. T. Swain, Low Temperature Research Station, Downing Street, Cambridge.

The thirteenth Symposium of the Society for Experimental Biology will be held at the University of Reading during September 15–19. The subject is "Utilization of Nitrogen and its Compounds by Plants". Further information can be obtained from the Hon. Symposium Secretary, Dr. J. F. Sutcliffe, 68 Half Moon Lane, London, S.E.24.

The British Society of Rheology is holding a meeting in the Department of Glass Technology of the University of Sheffield during April 15–17, 1959, on "The Rheology of the Glassy State". The meeting will discuss the mechanical and optical properties of inorganic and organic glasses and of high polymers in the glassy state. Intending contributors are invited to submit a title and detailed abstract (400–700 words) before September 15 to Dr. D. W. Saunders, British Rayon Research Association, Heald Green Laboratories, Wythenshawe, Manchester 22. Complete manuscripts will be required by mid-January 1959.

The third Congress of the Italian Society of Nuclear Biology and Medicine, arranged by the Medical Clinic of the University of Florence, will be held in Florence on November 3 and 4. All inquiries and applications for registration should be addressed to the Conference Bureau, Clinica Medica, Centro Radioisotopi, Viale Morgagni, Firenze, before September 15. Titles and short abstracts of papers (about 200 words) should be submitted before that date to the Segreteria della Società Italiana di Biologia e Medicina Nucleare, Clinica Medica, Pisa. The papers accepted will be published in a special issue of *Minerva Nucleare*.

BICENTENARY OF BOSCOVICH'S "THEORIA PHILOSOPHIÆ NATURALIS"

A MEETING was held on June 10 in the Yugoslav Embassy in London, at the invitation of the Ambassador, with Sir Harold Hartley in the chair, to celebrate the bicentenary of the publication in Vienna in 1758 of the "Theoria Philosophiæ Naturalis, redacta ad unicam legem virium in natura existentium" of Roger Joseph Boscovich, *S.J.* (born Ragusa, 1711; died Milan, 1787). The gathering represented many sciences and nationalities, reflecting the wide interests of a great eighteenth century figure.

Sir Harold Hartley opened with a brief sketch of Boscovich's relations with England and the Royal Society, of which he was made a Fellow on January 15, 1761, the same day as Sir Joshua Reynolds. Boscovich paid a visit to England in 1760, meeting many leading personalities, and incidentally served as Ambassador of the Free City of Ragusa, seeking to convince the British Government that Ragusa was not being used as a base by French warships. Sir Harold read a message from Prof. E. N. da C. Andrade describing the warm response of the Royal Society to Boscovich's visit, and of Priestley, Young, Faraday and Kelvin to Boscovich's ideas on the ultimate nature of matter, though the average student to-day may scarcely have heard of him.

Mr. L. L. Whyte then gave an address on Boscovich's theory of fundamental particles. Though Boscovich was recognized by his contemporaries as a distinguished mathematician, astronomer, geodesist, physicist, engineer and architect, as well as poet and diplomatist, his originality and influence were greatest in his "Theoria", where he developed in systematic form his doctrine of the constitution of matter. This was a kinematic theory of point particles[1], in which the traditional dualism (maintained by Newton and all Boscovich's scientific predecessors) of regions of space filled with matter contrasted with empty regions was discarded in favour of the simpler and more powerful 'Pythagorean' conception of spatial patterns of physical points, interacting in pairs in accordance with a single oscillatory law. Boscovich defined the general form of this law of central actions, but left the constants to be determined in the future. His theory was, in effect, a *programme for atomic physics* which a school of physicists has been carrying out since, until de Broglie introduced the wave-particle in 1923. Something might be gained by comparing the complex fields of 1958 with Boscovich's simple particles of 1758. Mr. Whyte showed that the great originality of Boscovich's conception had been recognized, not only by leading British and Continental scientists from 1760 to around 1920, but also by philosophers as varied as Nietzsche, Russell and Cassirer. It was of interest that both Nietzsche and Mendeléeff had put Boscovich with Copernicus as two of the most important and successful challengers of visual appearances.

A series of brief statements were then made on other aspects of Boscovich's work. Prof. Z. Kopal explained that Boscovich's contributions to astronomical science were in keeping with the trend of his times—the main achievements made during his lifetime were not in the field of discovery, but in the application of Newtonian gravitation to the theory of motion of celestial bodies, a work in which Boscovich took a prominent part. He shares honours with Laplace for the development of a method—still in use—for computation of cometary orbits based on three observations. As a professional astronomer for at least a part of his life-time, Boscovich perfected the stellar micrometer and, in 1770, became the founder and first director of the Brera (Milan) Observatory, which has remained in the forefront of Italian astronomical activities ever since.

Mr. C. A. Ronan discussed Boscovich's work in optics. He pointed out that in the eighteenth century corpuscular theories of light were the vogue but that Newton's theory of "easy fits of reflexion and refraction", which had been invoked to explain the partial reflexion and refraction occurring at the boundaries of surfaces of media having different refractive indices, was not fully appreciated. In Boscovich's theory of light the corpuscles were conceived of as rotating and having different polarities on their two sides, one being attracted by matter and the other repelled. Partial reflexion and transmission were thus explained. Moreover, this idea was invoked by others to explain, in conjunction with Boscovich's theory of matter, the penetration of light through solid bodies and the phenomena of astronomical refraction and of phosphorescence. Mr. Ronan also spoke of Boscovich's practical work in the design of an astronomical micrometer, his determination of the instrumental errors of the mural quadrant at Milan, his design of an equilibrium suspension for instruments of this kind, and his discussion of the residual errors inherent in such instruments and their reduction by appropriate design.

Dr. J. F. Scott considered Boscovich's contributions to pure mathematics, passing from his remarkable recognition of the possibility of a non-Euclidean geometry (for example, "these minds . . . would not seek, as our geometricians do, to rectify the parabola; they would endeavour, if one may use the words, to *parabolify* the straight line": "Theoria", § 116) to his advances in trigonometry, his brilliant essay on conic sections, his anticipation of the work of Legendre and Gauss on the calculus of observations, and his importance as one of the earliest foreign scholars to adopt the Newtonian theory of gravitation. Father L. J. Copplestone, *S.J.*, discussed Boscovich's atomism as an illustration of how a theory which is 'philosophical', as possessing wide implications, may provide the basis for a scientific theory which can be put to experimental test.

The Yugoslav Ambassador gave a lively sketch of Ragusa in Boscovich's time, and described how he established the first direct diplomatic relations between the Yugoslav peoples and Great Britain. Prof. I. Supek, president of the Boscovich Institute at Zagreb, brought greetings from the Yugoslav scientific societies and outlined the work of his Institute in research and teaching.

Sir Harold Hartley, in summarizing the contributions, stressed the part that Boscovich had played in establishing relations between the Southern Slavs and the United Kingdom, and the need for a biography of a great scientist recently unduly neglected. A scheme is under consideration for a volume combining a short biography with an extended report of the meeting covering additional aspects of Boscovich's scientific work.

---

[1] Recent studies of Boscovich's atomism, interpreting it as a kinematic theory, have been made by Whyte, L. L., *Nature*, **179**, 284 (1957), and *Notes and Records of the Royal Society*, **13**, 38 (1958); and by Jammer, M., "Concepts of Force", 170 (Harvard Univ. Press, 1957).

PHOTOCHEMICAL REACTIONS

THE Society of Physical Chemists of France organized a symposium on the transfer of light energy and photosensitization at the Physico-Chemical Laboratory of the University of Paris during May 27–30. In his introductory remarks, Prof. F. Perrin discussed the general principles of light-energy transfer and the life periods of activated molecules, fluorescence, chain reactions and their inhibition. D. Curie (Paris) presented the theoretical aspects of energy transfer and its mechanism in the crystals of luminescent minerals, such as zinc sulphide and potassium chloride. H. Haken (Erlangen) considered the theory of excitons and their role in the transfer of energy in the solid state. S. Nikitine (Strasbourg) described his experiments on the absorption, emission and reflexion spectra of thin layers of Cu_2O, HgI_2, PbI_2, CuBr, CuCl, TlI, TlBr, TlCl, CdS and CdI_2. Some experiments on the transfer of energy by excitons in cadmium sulphide were reported by E. Grillot (Paris), and N. Arpiarian (Paris) discussed the luminescence of zinc sulphide activated by gold and nickel at − 158° C.

A series of papers on the luminescence and energy transfer by organic compounds such as benzene, naphthalene, anthracene, chrysene, pyrene, dihydrodiphosphopyridine nucleotide, etc., were presented by workers from several countries. Other topics included the spectra of silver halides and the phenomena of optical sensitization and desensitization; photo-oxidations and photo-reductions and fluorescence of different organic compounds, colouring matters and their acceleration and inhibition; the transfer of light energy, fluorescence and mechanism of plant and algal photosynthesis. N. R. Dhar and co-workers (Allahabad) discussed their investigations on the increase of nitrogen fixation in soils on incorporating molasses, straw, grass, leaves, etc., by light absorption and calcium phosphates. The mechanism of this nitrogen fixation is based on the decomposition of water molecules into H and OH as in plant photosynthesis. As in animal metabolism and photosynthesis, phosphates are of great importance in nitrogen fixation. A. Szent-Györgyi (Massachusetts) contributed an important paper on the transfer of energy in muscles. This transfer is possible to distances greater than atomic dimensions.

As the world as a whole is short of food, intensive investigations on the acceleration of photosynthesis and soil nitrogen fixation are bound to be of great practical value.

On May 31 the Society celebrated its fiftieth anniversary at the Maison de Chimie, and addresses dealing with the progress of physical chemistry with special reference to France were delivered by Profs. R. Lucas, E. Bauer, R. Wurmser and A. Szent-Györgyi and the representative of the Minister of National Education in France.

THE GERMAN STARCH CONVENTION, 1958

THE International Starch Conference, held at Detmold during April 22–24, was well attended, with some 200 delegates from twenty countries.

In the section covering research and analysis, a paper was read by Dr. G. Gilbert (Birmingham), in which the action of air on aqueous solutions of starch was surveyed. An estimate has been made of the rate of hydrolysis of starch by pure water at 100° and 120° C., and it is found that the molecule of amylopectin is large enough to be affected by such hydrolysis during the dispersion of starch. The molecule of amylose, however, is too small to be affected by such hydrolysis, and it was suggested that oxidation by air contributes to the variation in the published values of the molecular weight of amylose. It was found possible to fractionate starch by dispersing it in cold sodium hydroxide under nitrogen and centrifuging the dispersion. Although sodium hydroxide is usually regarded as a good solvent for starch, the bulk of amylopectin was found to be quite insoluble in it under anaerobic conditions.

The development and present state of the starch industry in the United States was discussed by Dr. G. E. Hilbert (Washington). He reported recent success in growing a variety of maize, the starch from which contains 82 per cent amylose. It is hoped to raise this proportion to more than 90 per cent in the future. Amylose thus produced is cheaper than that obtained by chemical fractionation of starch. It is converted to the acetate, which is similar to cellulose acetate, and, moreover, it can also be digested in the stomach. Amylose acetate is therefore used for the production of such foodstuff adjuncts as sausage skins. Another development in the United States is the electrolytic oxidation of starch with periodic acid; the dialdehyde obtained is a good tanning agent for skins and is also used as a base for plastics.

Prof. M. Samec (Ljubljana) read a paper concerning the degradation of starch by γ-radiation. He reported in particular on the effects of the radiation derived from the betatron, X-rays and cobalt-60 on potato starch. Irradiation by cobalt-60 for 3 hr. was found to cause in starch complete loss of power to adsorb iodine. After 5 hr. the dialysable fraction had risen to 5·2 per cent and the reducing power had increased three-fold. After 7 hr. irradiation by cobalt-60, a dispersion of starch in water was reduced to nearly the same viscosity as pure water. It was also found that the amylopectin fraction had acquired an acid *p*H.

It has been known in the confectionery trade that starch syrups, made by acid hydrolysis of starch, tend to become 'brittle' and cloudy when containing a high proportion of dextrose. Dr. G. Graefe (Hamburg) informed the meeting that stable syrups of low monosaccharide content can be produced by using initial starch dispersions of high concentration. The hydrolysis is carried out in two consecutive stages: first using acid to dextrose-equivalent 50, followed by treatment with malt enzyme.

The ion-exchange properties of freshly prepared and aged starch with heavy water have been studied by M. Čeh (Ljubljana). He reported that the rate of exchange of hydroxyl groups of amylose and amylopectin with heavy water (D_2O) has been measured by means of infra-red spectroscopy on dried films. It was found that the capacity to exchange ions of aged amylose films is much smaller than that of fresh films, whereas amylopectin similarly treated undergoes no change. Treatment of aged amylose films with potassium hydroxide or hot water restores the capacity to exchange with heavy water almost to its former value.

A. W. Davies (London) discussed the production of vital gluten and its application in Great Britain. Vital wheat gluten fulfils a useful function in the fortification of flour or bread doughs, on which it confers increased volume, improved crumb structure, keeping quality and flavour, while enhancing its nutritional value. It permits the manufacture of bread suitable for inclusion in diets prescribed in the treatment of certain clinical conditions. Gluten, at one time considered only a waste product, is rapidly becoming indispensable to the baking industry.

At the conclusion of the conference a meeting was held to discuss the project for standardizing the analysis of starch and its products on an international level. Work has already been started by ten committees covering such items as viscosity, ash, colour and protein content of starches. It was resolved to ask the International Organization for Standardization to take this project under its ægis and to organize further work in the many countries interested in it.

E. DUX

THE WOOL INDUSTRIES RESEARCH ASSOCIATION

REPORT FOR 1957–58

THE report of the Director of Research of the Wool Industries Research Association for 1957–58*, presented at the thirty-ninth annual general meeting on March 25, notes that the increase in the statutory levy obtained by the Wool Textile Research Council and the Wool Textile Delegation has enabled the Association to obtain a maximum grant from the Department of Scientific and Industrial Research. Work at Torridon on behalf of the Technical Advisory Committee of the Federation of British Carpet Manufacturers on the relative merits of East Indian, New Zealand and British wools for carpets has shown that East Indian wools may have a density as much as 30 per cent less than that of New Zealand wools because of the presence of medullated or hairy fibres. Wear tests of an experimental carpet indicate that the abrasive machines used by the Association correctly assess the results likely to be obtained in actual wear. The Association has accepted a sponsored project which aims at combining the Association's shrink-resistant process with some method of stabilizing the fibre, so that the shape as well as the size of the garment will be retained after washing.

Experience with the pilot scouring machine has emphasized the need for a more versatile set for research. The study of the effect of the nature and amount of residual grease from scouring, together with added oil, on breakage of fibres and subsequent tear on combing points to the possibility of considerable improvement. Trials at Torridon have substantiated the claims of some firms that special fancies can reduce the amount of fettling, but a very solid foundation of fettlings may be built up, removal of which is difficult without damaging the cloth. It is now reasonably certain that the region of high twist occurs in the short portion of yarn between the delivery rollers and spindle tip when the carriage is at its innermost position. This short length is twisted twice on successive draws and the double twisting is not completely removed before the yarn is wound on the top. Accordingly, reducing the length of yarn at the innermost position may be advantageous. Sintered metal bearings for mule spindles impregnated with polytetrafluoroethylene have performed very well under test and are being tried in the mill.

The Raper auto-leveller draw-box is being modified for use with the rotating can method to permit a greater output and larger packages from the draw-box. Considerable progress is reported in the analysis of spinning end-breaks, and extensive experiments have been made to determine whether the 'resting' of wool at different stages in processing contributes to any desirable qualities in the finished fabric. Scouring experiments have been completed with white worsted and fancy woollen pieces, and special scouring routines have been developed to overcome difficulties experienced with wool 'Terylene' worsted cloths, while light bars and streaks in these cloths have been traced to exposure to light before scouring, when the oxidation of the combing oil is accelerated, and this is more readily removed from 'Terylene' as its state of oxidation advances. A survey of crabbing routines in the mills of twenty-three firms was completed, and in the Scottish Laboratory a study of the effect of steaming and storage on wool oils emphasized the importance of tryptophan in the discoloration of wool. Experiments at the Rowett Research Institute on the effect of a light–dark rhythm on the growth of wool indicated a seasonal variation in production of the wool, although the sheep were provided with a constant diet and maintained indoors. New methods have been applied to the fractionation of the soluble fractions and those precipitated iso-electrically from oxidized wool, and an apparatus was designed for following detergent action under the microscope, and another constructed for studying the visco-elastic properties of wool fibres over five decades below 1 cycle per second, under controlled conditions of temperature and humidity. Working at very high dilution to minimize association, infra-red spectroscopy has shown that both phenol and pyrrole react with the CO group of the secondary amide N-*n*-butylacetamide in carbon tetrachloride as solvent, and combination of neither compound with the amide modifies the infra-red absorption band of the amide NH group.

---

* Wool Industries Research Association. Report of the Director of Research for 1957–58. Pp. 30. (WIRA Publication No. 211.) (Torridon, Headingley, Leeds: Wool Industries Research Association, 1958.)

In his chairman's address at the annual general meeting, Mr. John Foster Beaver, reviewing changes in the circumstances and outlook of the Research Association, after a reference to its pioneering work on the control of relative humidity and on the fundamental properties and modes of operation of materials and processes used in the industry, said that the problem to-day was rather the significance for individual processing of the new knowledge being obtained from many other sources also. The Research Association had accordingly departed considerably from concentration on long-term research and was paying more attention to the immediate needs of the industry. During the past year more than 1,500 reports on consulting work were sent to members, and apart from solving an immediate difficulty, such reports indicate more general lines of research. For example, consulting work on stripey and barry pieces had led to an extensive programme on the effect of winding, warping and weaving tensions on the appearance of fabrics, which had indicated the degree of control required in these processes. During the year a series of six industrial lectures were given at Torridon on Saturday mornings as a new means of liaison with industry, and the attendance at these lectures had been extremely good.

THE PRODUCTION ENGINEERING RESEARCH ASSOCIATION

THE new building of the Production Engineering Research Association of Great Britain was formally opened by the Right Hon. Lord Chandos, at the Melton Mowbray, Leicestershire, headquarters of the Association on July 3.

These new premises—which have cost £250,000, of which £100,000 has been contributed by the Department of Scientific and Industrial Research—comprise extensive workshops and laboratories for the investigation and development of production engineering techniques. They house machine-tools, recording and testing instruments and auxiliary equipment worth some £500,000.

The acquisition of these facilities constitutes a major stage in the development of the Association, which had been working in temporary accommodation —converted stables—since it was founded in 1946. The Association was sponsored in its initial stages by the Institution of Production Engineers, the Gauge and Tool Makers' Association, the Machine Tool Trades Association, the National Federation of Engineers' Tool Manufacturers and the Department of Scientific and Industrial Research, and had its origin in the Institution of Production Engineers' Research Department which was established at Loughborough College in 1939 under the direction of Dr. G. Schlesinger, formerly of the Technical University of Berlin. Dr. Schlesinger was succeeded by his deputy, Dr. D. F. Galloway, who has been director of research at the Production Engineering Research Association since its foundation.

The Production Engineering Research Association is a non-profit making institution, deriving its income of about £250,000 a year partly from the subscriptions of 640 industrial companies and partly from the Department of Scientific and Industrial Research. It has a staff of about 250, and was established to assist member firms with their particular production engineering problems, undertaking practical investigations in the workshop or laboratory where necessary. Information services and technical training facilities are also provided. Visits are made regularly to each member firm by liaison engineers, members' staff are encouraged to visit the Association's workshops and laboratories, and there is a mobile unit equipped with cinema-cum-lecture theatre, and demonstration bay. A form of associate membership has recently been introduced for technical colleges and universities in Britain and the Commonwealth.

The primary objective of the Association is "to secure economic savings by the prompt and effective application of improved production techniques in members' workshops". One company has been shown how to save about £40,000 a year in the production of a single component; another is saving £30,000 a year by the cold extrusion of electrical components which had previously been produced by machining. Facilities are available for determining the causes of failure of components, for the selection and heat-treatment of materials, for testing lubricants, and for hardness and precision measurement.

But although mainly concerned with the solving of specific problems of member firms, much of the Association's work—particularly on metal-forming and metal-cutting techniques, for which it is very well equipped—is of general interest and application. From the point of view of those engaged in fundamental production engineering research in the universities, one can but regret that the private and confidential consulting nature of the Association's special investigations and development projects prevents the publication of findings which would undoubtedly be of considerable interest and value. Although it is recognized that the Production Engineering Research Association has an obligation to undertake investigations which bring immediate material benefits to the companies that finance its activities, it is to be hoped that as the Association further develops, and particularly in so far as it is a Government-sponsored research unit, the members of its team will be given freedom to initiate, pursue and publicize more work of a more fundamental character.

N. A. DUDLEY

ELECTRONIC COUNTING AND SIZING OF BACTERIA

By HERBERT E. KUBITSCHEK
Division of Biological and Medical Research, Argonne National Laboratory, Lemont, Illinois

THE resistance method of counting and sizing particles in suspension[1] used for counting blood cells[2,3] has been extended to counting and sizing bacteria. This method measures the resistance of a conducting solution as a particle passes through an aperture. For this purpose, a Coulter counter (Coulter Electronics, Chicago) was modified in our laboratory. The original aperture, about 100μ in diameter, was replaced by a smaller one, some 10μ in diameter, through a glass sheet about 50μ thick. The circuitry of the counter was modified to prevent multiple recording of a given cell, and a pulse-height analyser was added to allow a more direct measurement of the distribution of cell volumes. Size distributions for a 4-hr. broth culture of *Escherichia coli*, strain *B*, and for *Bacillus megaterium* spores are shown in Fig. 1. Both suspensions were diluted in 0·1 *N* hydrochloric acid for counting and sizing. Other diluents which have been used are saline, buffers, and nutrient broth. This method of sizing should be applicable to any stable suspension of particles in an electrolyte, provided that the particle conductivity is either less, or only slightly greater, than the conductivity of the solution. It is particularly applicable to sizing biological cells, which have very high specific resistance to direct current.

The resistance method of counting and sizing has the following advantages over optical methods. First, the volume of each particle is measured, rather than some accidental value for an optical cross-section, the latter being a poor measure of particle size for particles of unknown shape. Secondly, in the presence of a background of small particles the signal-to-noise ratio is greater when volume is measured than when a cross-section is measured; the signal-to-noise ratio is further improved by the action of the aperture as a filter for large unwanted particles. Finally, the counter is simple to operate: samples are readily interchanged, and no optical apparatus is needed to view the particles.

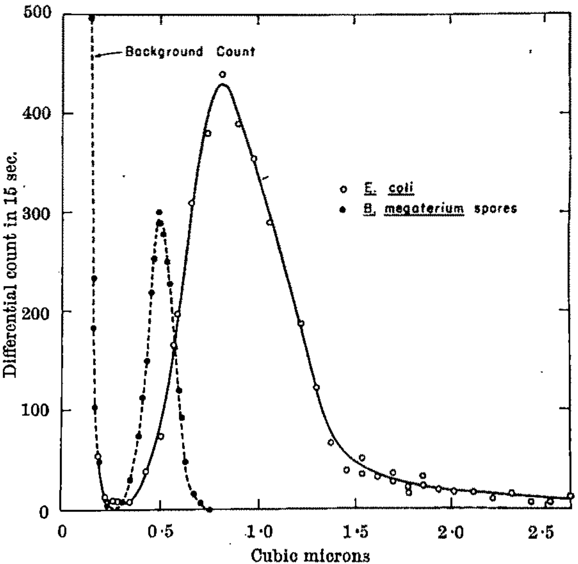

Fig. 1. Volume distribution of cell sizes of *E. coli* and *B. megaterium* spores

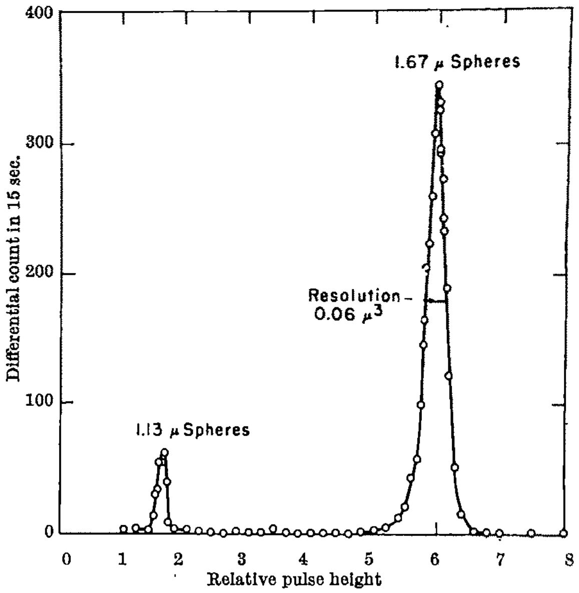

Fig. 2. Relative pulse-height distribution obtained with a mixture of 1·13μ and 1·67μ polystyrene spheres

To test the accuracy of counting, polystyrene latex spheres (kindly supplied by Dr. John Vanderhoff, Dow Chemical Co.), 1·13μ and 3·2μ in diameter, were suspended in saline and counted visually with the aid of a hæmocytometer to obtain absolute counts. The results were compared with values obtained with the counter. Corresponding determinations agreed within the standard error of 2 per cent of the mean. The counter is, therefore, an instrument for absolute counting of spheres at least as large as 30 per cent of the diameter of the aperture.

It can be shown that the change in the resistance of the aperture as a particle passes through it is proportional to the volume *v* of the particle, provided that the greatest cross-sectional area *a* of the particle is sufficiently small (and, of course, that the particle is shorter than the length of the aperture). For example, if the particles are right cylinders of resistivity ρ with axes aligned with the axis of the aperture, and if *A* and *V* refer to the cross-sectional area of the aperture and its volume, respectively, and ρ_0 and Ω the resistivity and the resistance in the absence of particles, then the fractional change in resistance of the aperture due to a single particle is:

$$\frac{\Delta\Omega}{\Omega} = -\frac{v}{V}\frac{\Delta\rho}{\rho}\left(1-\frac{a}{A}\frac{\Delta\rho}{\rho}\right)^{-1}$$

$$\text{where } \Delta\rho \equiv \rho - \rho_0$$

When $\rho \gg \rho_0$ the change in resistance with respect to volume is linear to 1 per cent for right cylinders with diameters less than 10 per cent of the diameter of the aperture. This restriction upon particle diameter for linearity of sizing will be less severe when the resistivity of the particle is not widely different from that of the solution, and it also will be reduced for particles with variable cross-section. (Particles with indentations are not considered here.)

To calibrate the counter for sizing, the relative diameters of 1·13-μ and 1·67-μ spheres were first determined by optical microscopy and by sedimentation in a sucrose gradient. The sucrose gradient measurements were kindly performed by Dr. John F. Thomson of this laboratory. Then the particles were sized electronically and gave, within 1 per cent, the same volume ratio.

The present resolution in volume determination varies between 0·04 and 0·06 cubic microns, corresponding to a linear resolution of about 2 per cent of the diameter for 1-μ spheres. This resolution is the observed half-width at half the height of the peak of the distribution, as in Fig. 2, observed with polystyrene spheres, which have a standard deviation in diameter of less than 1 per cent. The smallest particle volume which can be measured with the present aperture is about 0·2 cubic microns, as is evident from Fig. 1. This limit is set by the noise generated within the aperture, as well as the lesser noise in the electronic circuitry. The noise generated within the aperture is due to the electric current, to debris and, presumably, to localized heating within the turbulent stream.

This work was performed under the auspices of the U.S. Atomic Energy Commission.

INFLUENCE OF WATER ON THE PHOTOLYTIC DECOMPOSITION OF OZONE

By W. D. McGRATH and PROF. R. G. W. NORRISH, F.R.S.
Department of Physical Chemistry, University of Cambridge

EARLY work on the photolysis of dry ozone[1] established that the quantum yield was as high as 6·7 for light of wave-lengths between 2080 and 3130 A. Photolysis by visible light[2], however, always gave small quantum yields, the highest values being between two and three.

The fact that water vapour exerts a strong influence on the photolysis was clearly shown by Warburg and by Forbes and Heidt[3], who found that quantum yields varying from 1·6 to 130 could be obtained when ozone was mixed with water vapour and photolysed by light of wave-lengths 2800, 2540 and 2100 A. Forbes and Heidt were able to show that the quantum yield φ was roughly proportional to $\sqrt{[H_2O]}$. This and other experimental findings can be derived from a simple steady-state treatment of the system described later, involving the assumptions that the concentration of oxygen atoms at any time is small and that they are removed by reaction with water and not with ozone. The initiation reactions can then be represented by the three reactions:

$$O_3 + h\nu \rightarrow O_2 + O \tag{1}$$

$$O + O_2 + M \rightarrow O_3 + M \tag{2}$$

$$O + H_2O \rightarrow 2OH \tag{3}$$

which lead to the propagation reactions discussed below.

The results obtained from the early experiments on wet and dry ozone thus indicated that a chain mechanism is operative in both cases when ultra-violet light is used, and that the chain-length can be much greater when water vapour is present. In the case of the dry ozone, a simple atom chain-mechanism is inadequate to explain these results and it is necessary to invoke an energy chain, involving some form of excited oxygen. Absorption of light by ozone undoubtedly results in the production of one oxygen atom according to (1). For visible light this atom can only be in its ground-state ^3P. At wave-lengths less than 3100 A., however, dissociation can yield $O_2(^1\Delta g) + O(^1D)$. Subsequent reaction of either oxygen atom can then liberate a large amount of energy to produce some form of excited oxygen molecule according to the reaction:

$$O + O_3 \rightarrow O_2^* + O_2 \tag{4}$$

Early workers mostly assumed the excited state to be the electronic $^1\Sigma g^+$, but no direct evidence for this was available[4]. Using the technique of flash photolysis and kinetic spectroscopy, we were able to show that under isothermal conditions, that is, with an excess of inert gas, reaction (4) resulted in the production of vibrationally excited oxygen molecules, rotationally cold and in their electronic ground-states[5]. These molecules have sufficient energy to propagate a chain according to:

$$O_2^* + O_3 \rightarrow 2O_2 + O \tag{5}$$

Although ^3P oxygen atoms in reaction (4) are capable of releasing sufficient energy to account for the highest value of v'' observed (63·2 kcal./mole) the evidence was not conclusive in favouring $O(^3P)$ as responsible for the production of O_2^*.

Our recent work will now be outlined in brief. This, together with considerations of earlier work on the photolysis of wet and dry ozone by ultra-violet light, indicates beyond reasonable doubt that it is the $O(^1D)$ atom which is responsible for the chain-mechanism in both cases.

A very significant fact to emerge from the steady-state photolysis of dry ozone is that, when visible light is used, the value of the quantum yield φ is always small. Values have been obtained, however, between 2 and 3, under certain conditions, indicating that although $O(^3P)$ is not an efficient chain propagator it can initiate chains to a limited extent. This conclusion is supported by the work of Benson and Axworthy[6] on the pyrolysis of concentrated ozone mixtures with oxygen. They claim that the kinetics of the thermal decomposition can be explained without postulating an energy chain, and base their conclusion on the fact that, according to their interpretation, the O_2^* produced in reaction (4) with $O(^3P)$ must lose its excitation more rapidly than it can transfer it to ozone and bring about dissociation.

Using the technique of flash photolysis, outlined in a previous paper[5], we have now been able to show that absorption due to oxygen with v'' up to 17 can be detected immediately after dissociation of dry ozone

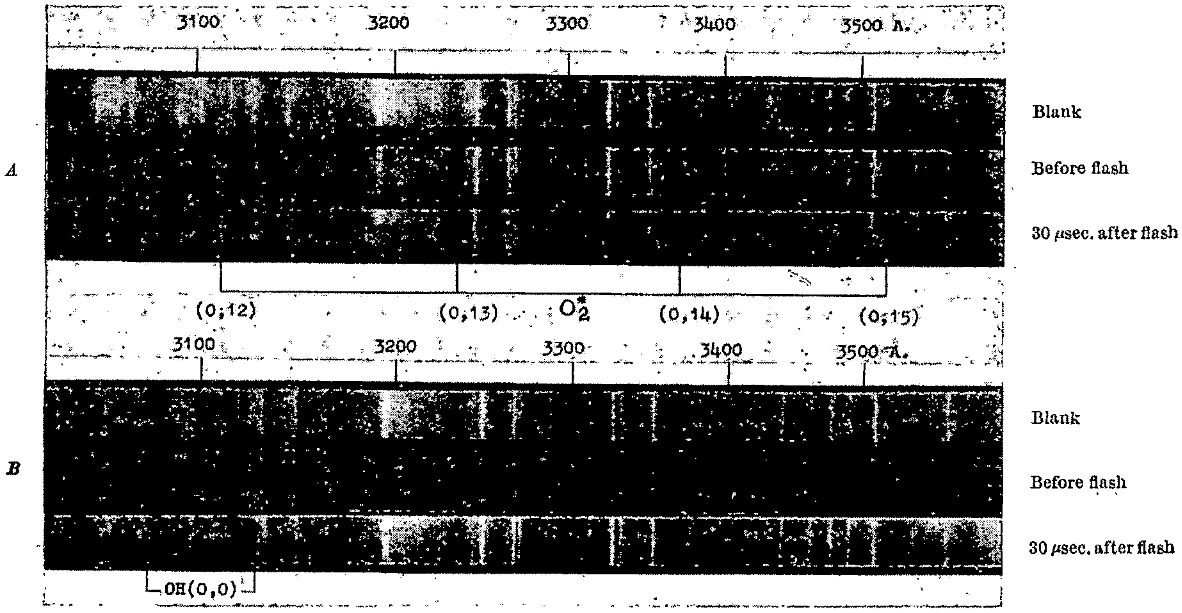

Fig. 1. Flash photolysis of ozone. *A*, dry ozone; mixture ratio ozone/nitrogen 1/100; ozone pressure 5 mm. mercury; *B*, wet ozone, mixture ratio ozone/water/nitrogen 1/3/100; ozone pressure 5 mm. mercury. Flash energy, 1,620 J.

by the flash. Repeated experiments with various mixture ratios and different partial pressures of ozone failed to detect any absorption with higher values of v''.

By introducing varying amounts of water vapour into the ozone/nitrogen mixtures we have been able to show that the effect of water on the photolysis can be attributed to the participation of OH radicals. With a mixture of ratio ozone/water/nitrogen (1/3/100) and a partial pressure of ozone of 5 mm. mercury, absorption due to OH can be detected at the shortest time attainable after flashing. The absorption is strongest at this time and decays relatively slowly. At the same time, production of vibrationally excited oxygen molecules is suppressed.

Production of OH radicals in these experiments must be brought about by reaction (3). For $O(^3P)$ this reaction is 16·8 kcal./mole endothermic, whereas for $O(^1D)$ it is 29·2 kcal./mole exothermic. It would seem certain, therefore, that under the conditions used in our experiments a considerable concentration of $O(^1D)$ atoms is produced, and that they must react preferentially with water to the exclusion of the reaction with ozone which forms the vibrationally excited oxygen in dry ozone. These facts are strikingly apparent in Fig. 1, in which corresponding mixtures of ozone and nitrogen are flashed under wet and dry conditions. Series *A* using dry ozone shows strong Schumann–Runge absorption; series *B*, with 15 mm. mercury of water vapour added, shows strong OH absorption and none due to O_2^*. In the figure only the (0,0) head of OH is shown. In agreement with this, Kistiakowsky[2] showed that decomposition in red light, which must involve ^3P oxygen atoms, is unaffected by water vapour.

These experiments indicate that the water molecules are very effective at mopping up $O(^1D)$ atoms and that it is this species which is responsible for the production of O_2^* during the photolysis of dry ozone. Subsequent reactions of the OH radical can now be written down to account for the high quantum yields previously observed as follows:

$$OH + O_3 \rightarrow HO_2 + O_2 + 42 \text{ kcal./mole} \quad (6)$$

$$HO_2 + O_3 \rightarrow OH + 2O_2 + 27 \text{ kcal./mole} \quad (7)$$

together with the possible chain-terminating reactions

$$2HO_2 \rightarrow H_2 + 2O_2 \text{ neutral} \quad (8)$$

$$2OH \rightarrow H_2 + O_2 + 12 \text{ kcal./mole} \quad (9)$$

$$2OH \rightarrow H_2O_2 + 46 \text{ kcal./mole} \quad (10)$$

$$2HO_2 \rightarrow H_2O_2 + O_2 + 31 \text{ kcal./mole} \quad (11)$$

This scheme, together with reactions (1), (2) and (3), leads to the following approximate formulæ for the quantum yield in wet ozone. In deriving the equation, k_6 and k_7 have been taken as equal and only one termination reaction is postulated.

$$\varphi = [O_3]\sqrt{\frac{K[H_2O]}{(k'[O_2][M] + k''[H_2O]I_{\text{abs.}})}} \quad (12)$$

For the case when a large amount of oxygen is present, which was so in the work of Heidt and Forbes, this approximates to:

$$\varphi = [O_3]\sqrt{\frac{K[H_2O]}{K'[O_2][M]I_{\text{abs.}}}} \quad (13)$$

If the light absorption is weak $I_{\text{abs.}} = kI_0[O_3]$ and

$$\varphi = \sqrt{\frac{K[O_3][H_2O]}{K''[O_2][M]I_0}} \quad (14)$$

These equations give the observed experimental facts such as the square root dependence of φ on the concentration of water.

Obviously from such a scheme high quantum yields are possible even when small amounts of water vapour are present, since the activation energies of (6) and (7) are not likely to be high.

The reason why $O(^3P)$ cannot propagate chains as readily at $O(^1D)$ in the photolysis of dry ozone is not entirely clear. Reaction (4) with $O(^3P)$ is 93 kcal./mole exothermic, and we have pointed out[7] that such a reaction could produce an oxygen molecule with a non-equilibrium value of vibrational energy well in excess of that required to dissociate ozone to ground-state molecules and atoms according to (15):

$$O_2^*(^3\Sigma g^-) + O_3(^1A) \rightarrow 2O_2(^3\Sigma g^-) + O(^3P) \quad (15)$$

The reaction requires 24 kcal./mole, which could be furnished by only 26 per cent of the total energy liberated in reaction (4). It may be concluded that $O(^3P)$ does not readily generate oxygen molecules with sufficient excitation for chain propagation.

For the production of $O(^1D)$ the primary step in the photolysis by ultra-violet light must be either:

$$O_3(^1A) \xrightarrow{h\nu} O_2(^1\Delta g) + O(^1D) - 91 \text{ kcal./mole} \quad (16)$$

$$\text{or } O_3(^1A) \xrightarrow{h\nu} O_2(^1\Sigma g^+) + O(^1D) - 106 \text{ kcal./mole} \quad (17)$$

Reaction (16) requires light of wave-length < 3100 A. and (17) wave-length < 2680 A. Subsequent reactions of the $O(^1D)$ according to (18):

$$O(^1D) + O_3(^1A) \rightarrow O_2^*(^3\Sigma g^-) + O_2(^3\Sigma g^-) \quad (18)$$

yield 138 kcal./mole, and it has been shown in our previous paper[7] that a high proportion of this energy appears as vibrational excitation of one of the oxygen molecules produced. Considerations of spin conservation rule out the production of excited singlet states in this reaction such as $O_2(^1\Delta g)$ or $O_2(^1\Sigma g^+)$.

Now in order for the chain to be propagated in dry ozone, the O_2^* produced in reaction (4) must in turn produce another $O(^1D)$ by reaction with ozone, according to:

$$O_2^*(^3\Sigma g^-) + O^3(^1A) \rightarrow 2O_2(^3\Sigma g^-) + O(^1D) \quad (19)$$

This requires 70 kcal./mole and hence only those O_2^* molecules with vibrational energy in excess of this will be effective. It is very significant that the highest value of v'' observed in the flash photolysis of ozone is 17, which corresponds to an energy of 66·7 kcal./mole—just too small to bring about reaction (19)—but the following value of v'', that is, 18, corresponding to 70 kcal./mole, is missing. It can be reasonably concluded that all such molecules with 18 or more quanta react by (19) so rapidly that no appreciable concentration builds up to enable their detection by spectroscopic means.

The argument outlined here explains adequately all the features of the photolysis of both wet and dry ozone with light of various wave-lengths. It seems certain that the chain mechanism in both cases is ultimately due to the presence of the $O(^1D)$ atom, which, because of its high energy and ability to react according to (4) without any activation energy, can either produce O_2^* molecules with sufficient energy to propagate a chain reaction, or when water vapour is present to react according to (3) and yield OH radicals from which a radical-propagated chain is derived.

ENDOGENOUS METABOLISM IN BRAIN CORTEX SLICES

By Dr. R. VRBA and JAROSLAVA FOLBERGR
Institute of Industrial Hygiene and Occupational Diseases, Prague 2

IT is known that brain cortex slices take up a considerable amount of oxygen when incubated without added substrate[1,2]. The consumption of lactic acid and carbohydrate contained in brain slices accounts for only a fraction of the observed total uptake of oxygen[2]. It is well known that ammonia formation is considerably increased when nervous tissue, and especially brain cortex slices, are incubated *in vitro* without added substrate[1–9]. It seems probable, therefore, that the endogenous metabolism of brain slices is connected with ammonia formation[3].

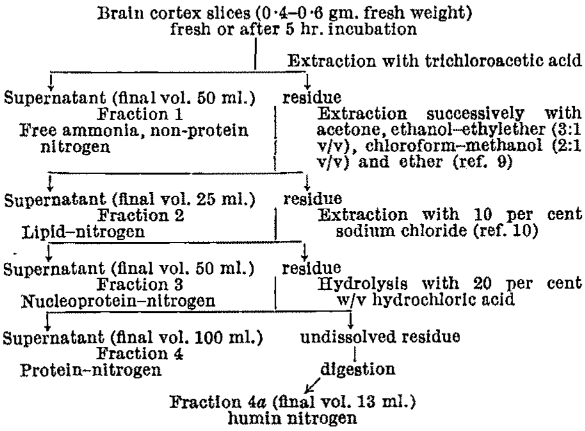
We have observed that ammonia formation in brain slices is accompanied not only by an increase of non-protein nitrogen, but also by a marked increase of lipid-nitrogen, that is, nitrogen-containing substances are transferred from the protein fraction to the lipid fraction[6,9]. It is suggested that all three processes, namely, the increase of ammonia, of non-protein nitrogen and of lipid nitrogen, may have a common root. The present experiments were an attempt to find this common source of nitrogen in brain slices, by using a simple fractionation of nitrogenous compounds in fresh and incubated slices to account quantitatively for all transfers of nitrogen.

In these experiments, only large batches of slices were used for analysis (400–600 mgm. wet weight). This diminishes the effect of individual variation between slices. All results are expressed as percentages of the total nitrogen of the slices instead of the wet weight, because despite the usual precautions it is difficult to remove the adhering liquid in a way that can be reproduced.

Each experiment was performed with twelve Warburg vessels, each containing 4 ml. of Krebs–Ringer phosphate saline without added substrate. To six vessels (non-incubated controls) 1 ml. of 50 per cent w/v trichloroacetic acid was added before the slices were introduced. Freshly cut guinea pig brain cortex slices (60–100 mgm. wet weight) were introduced into all vessels, and the six vessels not containing trichloroacetic acid were incubated in a Warburg apparatus for 5 hr. in oxygen, with shaking, at 37° C. After the incubation the vessels were detached from the manometers, and after the addition of 1 ml. of 50 per cent w/v trichloroacetic acid to each incubated vessel, the contents of these were combined. The contents of the unincubated vessels were similarly treated. Thus, two large samples of fresh and of incubated slices were obtained. Trichloroacetic acid extracts were prepared as described in more detail elsewhere[9]. The final volume of the extract was 50 ml. The rest of the tissue was then fractionated into various main groups of nitrogenous compounds according to scheme 1.

Aliquots of all four fractions were digested; free ammonia was estimated[1] in fraction 1. The digests were distilled in a Markham apparatus[12] and ammonia estimated by nesslerization.

Scheme 1. FRACTIONATION OF SLICES INTO GROUPS OF NITROGENOUS COMPOUNDS



Brain cortex slices (0·4–0·6 gm. fresh weight)
fresh or after 5 hr. incubation
Extraction with trichloroacetic acid
Supernatant (final vol. 50 ml.)
Fraction 1
Free ammonia, non-protein nitrogen
residue
Extraction successively with acetone, ethanol–ethylether (3:1 v/v), chloroform–methanol (2:1 v/v) and ether (ref. 9)
Supernatant (final vol. 25 ml.)
Fraction 2
Lipid–nitrogen
residue
Extraction with 10 per cent sodium chloride (ref. 10)
Supernatant (final vol. 50 ml.)
Fraction 3
Nucleoprotein–nitrogen
residue
Hydrolysis with 20 per cent w/v hydrochloric acid
Supernatant (final vol. 100 ml.)
Fraction 4
Protein–nitrogen
undissolved residue
digestion
Fraction 4*a* (final vol. 13 ml.)
humin nitrogen

Results of five experiments are recorded in Table 1. It may be seen that during incubation an increase of ammonia nitrogen, of non-protein nitrogen and of lipid nitrogen occurs; this increase is quantitatively accounted for by the decrease of the nitrogen in the protein and nucleoprotein fraction.

The density of the sodium chloride extract was measured in the ultra-violet, using the Soviet spectrophotometer *SF*-4, and absorption curves constructed. The measured densities were referred to 10 mgm. of total nitrogen in slices (Fig. 1). It may be seen that extracts of incubated slices show lower absorption, confirming the results in Table 1, namely, that during incubation of slices a degradation of the nucleic acids occurs. Evaluation of the results of four experiments performed are recorded in Table 2.

The fact that nucleic acids are metabolized during incubation of brain cortex slices raises the problem of the fate of the pentose in these compounds. The Mejbaums orcinol reagent was added to aliquots of the sodium chloride extract and pentoses were estimated colorimetrically[11]. As bound pentoses give a different density from free pentoses with this method, no standards were used, but the densities of extracts of fresh slices, after correction to the standard weight of 10 mgm. of total nitrogen in slices, were compared with similarly recalculated densities of the sodium chloride extracts of the incubated slices. A significant decrease of pentoses in this fraction occurs (Table 2). The deficit of pentoses in the nucleoprotein fraction cannot be accounted for by an increase of pentose in the fraction soluble in trichloroacetic acid, for an even more marked decrease of pentoses was found in this fraction by the same procedure (Table 2).

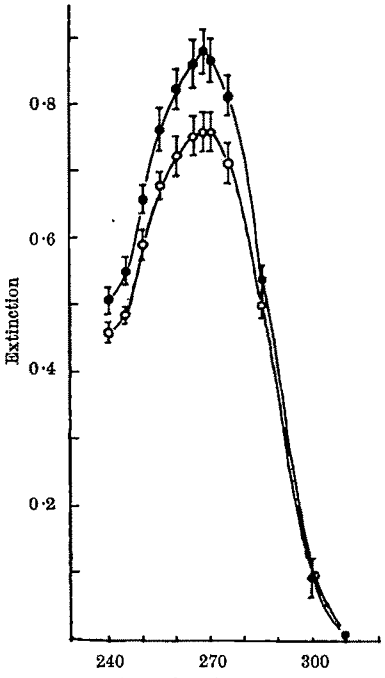


Fig. 1. Ultra-violet absorption curve of the sodium chloride extract of four experiments: ●—●, before; ○—○, after 5 hr. incubation at 37° C. with oxygen

Table 1. NITROGEN CHANGES IN GUINEA PIG BRAIN CORTEX SLICES AFTER 5-HR. INCUBATION IN KREBS–RINGER PHOSPHATE SALINE WITHOUT ADDED SUBSTRATE

Fraction	Initial	Final	Average difference	Balance
Free ammonia (ref. 1)	0·55 ± 0·08	2·73 ± 0·13	+ 2·18	+ 8·64
Non-protein nitrogen (not including free ammonia)	7·14 ± 0·54	11·14 ± 0·24	+ 4·00	
Lipid nitrogen	5·27 ± 0·57	7·73 ± 0·45	+ 2·46	
Nucleoprotein nitrogen	21·77 ± 1·49	17·65 ± 0·31	– 4·12	– 8·63
Protein nitrogen	61·87 ± 1·59	57·92 ± 0·62	– 3·95	
Humin nitrogen	3·39 ± 0·09	2·83 ± 0·17	– 0·56	

Results are expressed as percentages of total nitrogen. The means and standard errors of five experiments are given. All differences are significant ($P < 0·01$)

Table 2. PENTOSES AND NUCLEIC ACIDS AFTER 5 HR. INCUBATION OF BRAIN CORTEX SLICES IN KREBS–RINGER PHOSPHATE SALINE WITHOUT ADDED SUBSTRATE

1 Pentoses in Fraction 1 (trichloroacetic acid extract)	2 Pentoses in Fraction 3 (sodium chloride extract)	3 Nucleic acids in Fraction 3 (optical density of the extract at 268 mμ)
62·3 ± 2·7	82·8 ± 6·9	86·9 ± 5·7

Results are expressed as percentages of initial values. The means and standard errors of four experiments are given

Only small, constant amounts of orcinol-positive substances were found in acid hydrolysates of evaporated aliquots of the lipid fraction, as in the protein fraction. The conclusion to be drawn from these experiments is that degradation processes in the protein and nucleoprotein fraction, occurring during incubation of brain cortex slices, account for the accumulation of ammonia, of non-protein nitrogen and of lipid nitrogen, and are accompanied by utilization of endogenous bound pentose.

OBSERVABILITY OF SPONTANEOUS TEMPERATURE FLUCTUATIONS

By T. P. GILL

Weapons Research Establishment, Salisbury, South Australia

A NUMBER of authors, for example, Milatz and van der Velden[1], Daunt[2] and Chasmar *et al.*[3], have discussed the fundamental limits to the sensitivity of bolometers and other thermal radiation detectors. The two natural limits are Johnson noise and spontaneous temperature fluctuations in the case of the bolometer element. The following brief discussion illustrates the way in which these fluctuations may be treated.

The most important symbols used are :

$\overline{\Delta V_\theta^2}$, mean square thermal noise voltage ;
$\overline{\Delta V_J^2}$, mean square Johnson noise voltage ;
k, the Boltzmann constant (watt deg.$^{-1}$) ;
T, absolute temperature of bolometer strip (deg. K.) ;
T_0, absolute temperature of environment (deg. K.) ;
r, electrical resistance of bolometer strip (ohm) ;
Δf, narrow frequency band-width in which observations of noise are made ;
i, measuring current in bolometer (amp.) ;
β, temperature coefficient of resistance of bolometer strip, defined in this case as $(1/r)(\mathrm{d}r/\mathrm{d}T)$;
R, real part of thermal impedance of bolometer strip to surroundings at frequency f cycles/sec. ;
A, total area of bolometer (cm.^{2}) ;
σ, Stefan–Boltzmann constant (watt cm.$^{-2}$ deg.$^{-4}$) ;
η, bolometer emissivity.

The fluctuating voltage across the bolometer terminals, which ultimately defines the minimum detectable power, is usually derived from the following relations :

$$\overline{\Delta V_J^2} = 4kTr\Delta f \qquad (1)$$

$$\overline{\Delta V_\theta^2} = i^2r^2\beta^2 \,.\, 4kT^2R\Delta f \qquad (2)$$

for Johnson noise and temperature fluctuations, respectively.

The total mean square noise voltage is thus found to be :

$$\overline{\Delta V^2_{\mathrm{Tot.}}} = 4kTr\Delta f\,(1 + i^2r\beta^2TR)$$

In discussing the minimum detectable power of bolometers the next step is to introduce a formula for the sensitivity in volts per watt. However, it is proposed here to consider only the noise voltage appearing at the bolometer terminals. For sufficiently low frequencies, R can be taken as $(4\eta A\sigma T^3)^{-1}$ when the bolometer is operated *in vacuo*, and i^2r may be written as $\eta A\sigma(T^4 - T_0^4)$.

Thus,

$$\overline{\Delta V^2_{\mathrm{Tot.}}} = \overline{\Delta V_J^2}\{1 + \tfrac{1}{4}(1 - T_0^4/T^4)\beta^2T^2\} \qquad (3)$$

For a metal bolometer, βT is in the neighbourhood of unity, and since T_0 must be less than T we have :

$$\overline{\Delta V_J^2} < \overline{\Delta V^2_{\mathrm{Tot.}}} < 5/4\,\overline{\Delta V_J^2}$$

Unless β can be increased by about an order, $\overline{\Delta V_\theta^2}$ will usually be small compared with $\overline{\Delta V_J^2}$. Unfortunately, materials which have a large β usually show current noise which masks $\overline{\Delta V_J^2}$ as well as $\overline{\Delta V_\theta^2}$. The matter is made worse by the fact that the frequency spectrum of the current noise resembles that of $\overline{\Delta V_\theta^2}$ and both vary in a similar way with i. Valve noise in amplifiers also increases at low frequencies in a somewhat similar manner.

We may, however, question whether this procedure of adding $\overline{\Delta V_\theta^2}$ and $\overline{\Delta V_J^2}$ is in fact valid, since both types of fluctuation are manifestations of the same underlying phenomenon. If we cannot add these fluctuations, then the bolometer will be limited ultimately by Johnson noise, which implies that the presence and magnitude of spontaneous temperature fluctuations in bolometers should really be unobservable.

In general, it is quite wrong to expect to be able to derive fluctuations in various properties of a body from temperature fluctuations occurring spontaneously, using the normal temperature coefficient. For example, in a gas the random variations in pressure, density and temperature are not connected by the ordinary macroscopic gas laws—each of them is a different aspect of the statistical fluctuations in molecular position, velocity, etc., and they are not causally related in the sense that one can be regarded as giving rise to another. The concept of temperature itself requires careful examination in the microscopic case, since we find that heat flow is no longer simply related to temperature gradient. There are certain types of temperature-measuring devices, namely, those in which no power is supplied from outside, for which it can be shown that these spontaneous temperature fluctuations are inherently unobservable. This may be illustrated by two examples.

In the first, let us consider a very sensitive and delicate bimetallic strip which is used as a thermometer, the movement of its one free end being taken to indicate the temperature. It will undergo spontaneous fluctuations in temperature given by the well-known relation $\overline{\Delta T^2} = kT^2/c$, where $\overline{\Delta T^2}$ is the mean square temperature change and c is the thermal capacity of the body. If a temperature change of 1° C. produces a displacement S of the strip we might expect to observe a resulting fluctuation $\overline{\Delta x^2} = S^2kT^2/c$.

However, the strip must also execute Brownian motion, which is given by the relation $kT/2 = g\overline{\Delta x^2}/2$ (g being the stiffness of the strip) leading to $\overline{\Delta x^2} = kT/g$. It is clearly inadmissible to add these two fluctuations, since if we did so we would have a body with a mean kinetic energy (for this particular degree of freedom) in excess of the equipartition value.

For the second example we may consider a galvanometer, to the terminals of which a sensitive thermocouple is connected. Because of the equipartition law, the mean kinetic energy of the galvanometer suspension will be unaffected by any temperature fluctuations which may occur in the thermocouple, or for that matter by the presence or absence of the thermocouple, nor would the fluctuations exhibited by means of a valve amplifier exceed the normal Johnson noise (plus, of course, valve noise), provided always that the whole system is at the same temperature. This point is discussed in some detail by McCombie[4] and Jones and McCombie[5].

In considering the case of a galvanometer, Astbury[6] adds the fluctuations due to Johnson noise to the normal Brownian movement of the suspension. Even without the more sophisticated approach of Jones and McCombie it seems wrong to do this because of the resulting deviation from equipartition which could, in principle at least, lead to the establishing of a temperature gradient in a spontaneous manner. A somewhat similar operation to Astbury's is implied in a paper by Strong[7] and one dealing with thermopiles by Hornig and O'Keefe[8].

Referring to the bolometer, McCombie[4] says that, "unlike the thermocouple, [it] is not an equilibrium system. The strip, of which the change in temperature is to be measured, carries a steady current in order to convert changes in resistance into changes in voltage. There is, therefore, no reason to expect that the fluctuations can be discussed in terms of Nyquist's result". From this it is clear that to use arguments based on equilibrium conditions is unsound. Now the Nyquist–Johnson formula, equation (1), is, of course, based on equilibrium conditions but still is found to hold for metallic conductors even when they are carrying current. Equation (2) also may be derived from a consideration of equilibrium conditions (see ref. 2). It is, in fact, quite common to treat the bolometer as an equilibrium system, although this cannot be justified except by the correctness of the results obtained. In other words, if we are justified in treating the bolometer as an equilibrium system, it is not clear that we should expect to be able to observe spontaneous temperature fluctuations. If we are not so justified, our conclusions will be open to question in any event. It therefore seems desirable that the question should be examined experimentally.

I have carried out[9] a number of experiments with evaporated-gold bolometers as small as 0·2 mm. square, but in no case has a condition been achieved where the spontaneous fluctuations in temperature might be observed. The reason for this was mainly the fact that the gold in the thin film used had a temperature coefficient of resistance of the order of one-third of that of the bulk metal, which reduced βT to about 1/3 and would therefore have required the root-mean-square noise to be measured to much better than 5 per cent, which was beyond the capabilities of the equipment used. Current noise was also present in most cases, and even where it was small compared with Johnson noise could still mask any temperature fluctuations. Other considerations have prevented the subject being pursued, but it seems possible that the problem might be attacked using thin platinum strips, similar to those used by Chasmar and others[3].

It will be noticed that the thermal capacity of the bolometer does not enter into equation (3); but this does not mean that we can therefore use robust resistance thermometers. The apparent paradox is produced by our limiting ourselves to 'sufficiently' low frequencies, and a more complete analysis shows that in practice a very delicate device indeed must be used if we can realize the figure given by equation (3).

The arguments above are by their nature not rigorous, but nevertheless it is felt that a case has been established for reviewing the assumption that spontaneous temperature fluctuations are observable, as such, particularly in the case of the bolometer.

I wish to acknowledge my indebtedness to Dr. F. W. Woltersdorf, formerly of the Department of Supply, Commonwealth of Australia, for many fruitful discussions on the subject of this communication and allied topics, and to thank the Chief Scientist, Department of Supply, for permission to publish it.

LIVER GLUCOSYL OLIGOSACCHARIDES AND GLYCOGEN; EFFECTS OF STARVATION, GLUCOSE FEEDING AND INSULIN

By DR. HSIEN-GIEH SIE and PROF. W. H. FISHMAN

Tufts University School of Medicine and the New England Center Hospital, Boston, Mass.

RECENTLY, we have succeeded in isolating and identifying rat liver maltose, maltotriose and maltotetraose, and in recognizing higher members of an ascending homologous series of glucosyl oligosaccharides[1]. These were findings made unexpectedly during an investigation of the nature of glucosiduronic acids in liver.

The purpose of the present article is to present other results which justify the giving of more than passing attention to the question of the significance of these hepatic glucosyl oligosaccharides.

Male albino rats (250 gm.) were fasted for different lengths of time up to 24 hr. and then killed. The liver was removed and two 1-gm. portions of it were frozen (deep freeze) and analysed later for glycogen by Roe's method[2] and for glucosyl oligosaccharides by the method described in the following paragraph.

A 1-gm. specimen of liver was homogenized in 10 ml. of cold distilled water and was immediately deproteinized with 1 ml. 10 per cent zinc sulphate solution and 1 ml. 0·5 *N* sodium hydroxide solution. After centrifugation, the supernatant was collected, and washings of the precipitate (3 portions of 10 ml. cold water) were added to it. Supernatant and washings were pooled and treated with 3·0 gm. activated charcoal for 5 min. at room temperature. The charcoal was collected on a Buchner funnel and washed repeatedly with 20-ml. portions of water (total volume 250–500 ml.). The oligosaccharides were eluted from the charcoal with 3 × 20 ml.

Veterinary

VETERINARY PROTOZOOLOGY

U. F. Richardson, B.Sc., M.R.C.V.S.
S. B. Kendall, Ph.D., B.Sc., M.R.C.V.S.

For this second edition Richardson's well-known book has been completely rewritten and brought up-to-date with the addition of much new material. Each disease is considered under the heads of Morphology of the Parasite; Distribution and Transmission; Species Susceptible; Symptoms and Pathogenicity; Diagnosis, Treatment and Control. There is a separate section on Chemotherapy. 22s. 6d.

THE ALIMENTARY TRACT OF THE RUMINANT

D. Benzie and
A. T. Phillipson, M.A., Ph.D., M.R.C.V.S.
Rowett Research Institute, Aberdeen

This book consists of a short text and a large collection of reproductions of radiographs of the alimentary tract of the lamb, the kid goat, the calf and the adult sheep and goat. The reproductions which are supported by explanatory diagrams illustrate most of the movements that can be detected in the propulsion of food through the various compartments of the stomach of the ruminant. 27s. 6d.

LIVESTOCK IMPROVEMENT

J. E. Nichols, M.Sc., Ph.D.
Professor of Agriculture, University College of Wales

During the past decade there have been substantial increases in the volume and intensity of research into the ecological, genetical and physiological aspects of livestock improvement. This new, fourth, edition of Dr. Nichols' book has been revised in the light of the discoveries resulting from this research. 16s.

STOP WATCHES

for Scientific use

This 603 stop watch is ideal for research. It combines a fast escapement 1/10th. second with a split facility and a 30 minute recorder. It is also accumulative — enabling successive observation to be totalized. It is usually supplied complete with N.P.L. Certificate.

Repair service. Our skilled repair staff deals with all types of watches, clocks and associated equipment. "Crash" service—ring MUSeum 2255.

Sectional catalogues and leaflets available

Watches, stop watches and chronographs. Clocks: aircraft, domestic, industrial architectural and turret. Revolution counters, tachographs and associated equipment. Process timers and time interval meters. Electronic instruments.

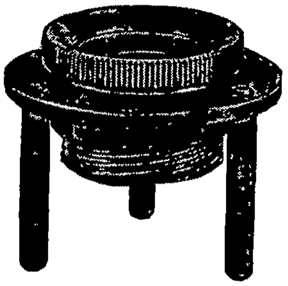
MAGNIFIERS



The tripod stand magnifier which is illustrated is one of the 200 different types described in our free booklet, "Magnifiers and Visual Aids". Hand reading glasses, watchmakers' eyeglasses, triple achromatic loupes, illuminated stand magnifiers, telescopic spectacles: all are included.

Please ask us to send a copy.

MACMILLAN BOOKS

Modern Science and the Nature of Life

WILLIAM S. BECK

Assistant Professor of Medicine, Harvard
Chief of Haematology Research, Massachusetts General Hospital

'Dr. Beck has written an excellent and enthusiastic account of the present position of biological science and sketched its relation to other branches of scientific and philosophical thought.'—*Sunday Times.* 15*s*

An Elementary Introduction to the Methods of Pure Projective Geometry

J. HEADING, M.A., PH.D.

This book has been written for students preparing for Scholarship examinations and for students attending any course on plane projective geometry, at a stage prior to that in which matrix techniques are applied to the subject. *With diagrams* 10*s*

Textbook of Economic Analysis

EDWARD NEVIN, M.A., PH.D.

An introduction to the groundwork of contemporary economic and monetary theory. Assuming no previous knowledge on the part of the reader, it sets out to explain the nature and scope of economic analysis, and then proceeds to an exposition of the modern theories of demand, supply, value and income distribution. Finally, the book deals with the issues arising from international transactions. *With diagrams* 18*s*

An Atlas of Airborne Pollen Grains

H. A. HYDE and K. F. ADAMS

This atlas is intended primarily as an aid to the identification of pollen grains in the fresh condition. The ninety-two species described are those which can be observed at a magnification of about 1,000 diameters. The book should be of value in studies of airborne pollen in general and in relation to hayfever, and, to a lesser degree, the pollen loads of bees, and pollen in honey and in peat. *Illustrated* 36*s*

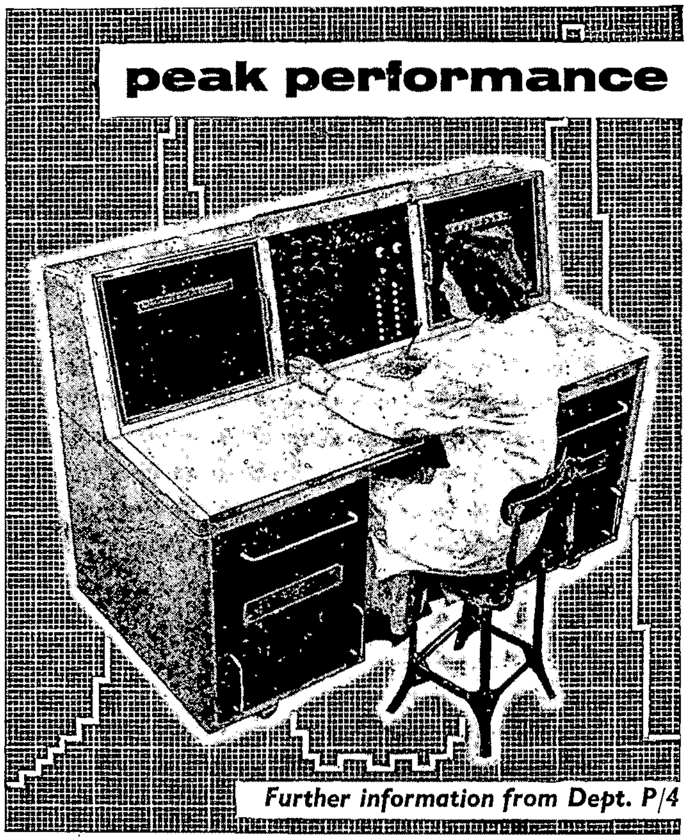
peak performance in polarography



—determines 0.0001 p.p.m.

The new MERVYN-HARWELL SQUARE WAVE POLAROGRAPH MARK III combines in one Instrument, all the special needs of the Polarographer who wishes to exploit fully the exceptional merits of this outstanding Analytical Technique.

- Extreme Sensitivity
- Exceptional Selectivity
- Completely self-contained
- Great Versatility
- Ultimate in convenience
- Resolves 20 m.v.
- Built-in cell, thermostat Nitrogen supply and recorder
- Reversible and Irreversible reactions
- All controls located and ganged for rapid and accurate operation.

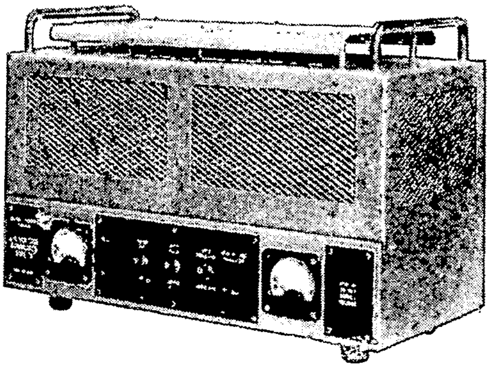
A. C. STABILISER

ENTIRELY ELECTRONIC IN OPERATION



PERFORMANCE DATA

STABILITY	±0.05 per cent for input voltage changes of at least ±10 per cent at all loads and for normal frequency variations.
REGULATION	Within ±0.1 per cent for changes from no load to full load.
WAVEFORM	Total introduced harmonic content within 3 per cent (mainly 3rd and 5th) under average conditions.
REACTIVE LOADS	Above performance maintained for loads of P.F. from 0.8 to unity, lagging or leading.
INPUT VOLTS	(Nominal) 210, 220, 230, 240 and 250 switch selected 200 V. on request.

GRUBB PARSONS

- ★ **Even greater constancy of output voltage than with earlier model.**
- ★ **Increased output—up to 1 amp.**
- ★ **Safety device incorporated to avoid any dangerous rise in output voltage in event of failure of any part of the unit.**
- ★ **Optional provision of voltmeter and ammeter to measure input and output voltages and output current.**
- ★ **Stabiliser can be adapted at small cost to stabilise the radiation emission from light sources such as filament lamps and Nernst filaments.**

Ups and downs . . .

on a surface that should be smooth are a constant source of trouble to the engineer. How is he to remove things that he may not be able to see ? The answer is to make them visible with an interferometer, which will show them plainly, even though they amount to no more than a fraction of the wavelength of light. We, of course, make all sorts of interferometers and interferometric apparatus—some for measuring lengths, some for increasing the resolving power of spectroscopic instruments, some for testing prisms and lenses, and some for examining surfaces and measuring their irregularities.

¶ The photograph shows a steel slip-gauge with a scratch across its surface, seen through a Hilger surface micro-interferometer. The interference fringes form a 'contour map' of the surface, and if the surface were truly flat, the fringes would be straight, parallel, and sharply defined.

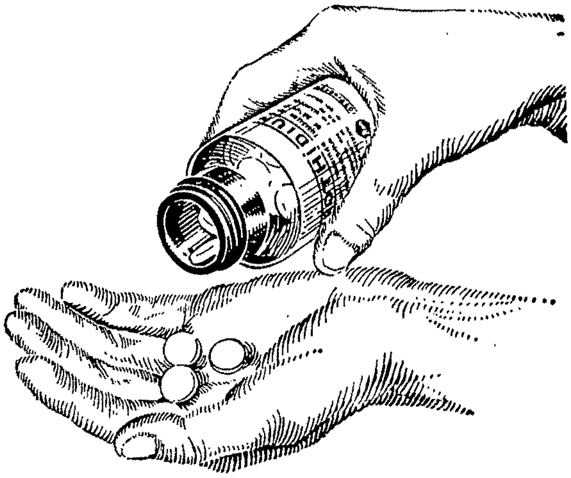
PROTHIDIUM



for the prophylaxis of bovine trypanosomiasis

Prothidium is given at a dosage level of 2 mg./kg. body weight and may be administered either subcutaneously or intramuscularly. At this rate, no acute or delayed systemic toxicity has been reported. Local reactions resemble those following the administration of other phenanthridine compounds.

As Prothidium is soluble in water its use as a solution gives it definite advantages over suspensions. It provides for more uniform absorption, it is quicker and more reliable in action and is easier to administer.

Prothidium is available as 0.5G tablets in bottles of 20 and 100.

portions of hot ethyl alcohol (95 per cent). Then the charcoal was transferred to a beaker and extracted with 2 × 20 ml. of hot ethanol, which was decanted and filtered finally through the original Buchner. An aliquot (0·2–1·0 ml.) of the alcoholic eluate was analysed by the Dische reaction[3]. The recovery of pure maltose when treated as above was 97 per cent and as little as 2–5γ of it can be measured. The results are expressed as mgm. of oligosaccharides per 100 gm. of liver in terms of the number of glucosyl residues. The results are shown in Fig. 1.

After 24-hr. starvation, glucose (2·0 gm. in 3·5 ml.) was administered by stomach tube. Of these animals, 6 received a second dose of 2·0 gm. of glucose 28 hr. after time zero. At the time-intervals indicated in Fig. 1, the animals were killed and their liver oligosaccharides and glycogen determined as described above.

It was observed that on starvation, rat-liver glycogen underwent a progressive and regular decline to disappearance-levels after 8 hr. In the case of the glucosyl oligosaccharides, a parallel decrease was observed but not to the same extreme degree as was noted for glycogen. In this regard, it may be reasoned that if the oligosaccharides were derived solely from glycogen breakdown, then coincident with the profound drop in liver glycogen one should expect to find a noticeable increment in liver oligosaccharides. This event did not occur.

The administration of glucose to starved rats caused a rapid restoration of liver glycogen to the pre-starved level, as expected. The amount of liver oligosaccharides increased also but at a slower rate than was the case for glycogen.

Liver glycogen and glucosyl oligosaccharides were determined 2 hr. after 6 rats received 4 units each of insulin (Lilly) subcutaneously (Fig. 2).

Insulin administration resulted in a characteristic marked decrease in hepatic glycogen[4]. This was accompanied by a parallel diminution in glucosyl oligosaccharides (Fig. 2). Qualitatively, similar results were obtained in rats starved for 24 hr. and then given glucose and insulin.

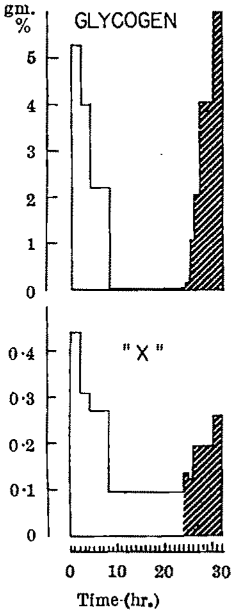

Fig. 1. Liver glycogen and glucosyl oligosaccharides ("X") in relation to hours of starvation and to subsequent glucose administration (shaded areas). The numbers of rats employed for each time-interval (hr.) were, respectively: 0–2, 11; 2–4, 4; 4–8, 5; 16–24, 10; 24–25, 6; 26–27, 6; 27–30, 6; 30–32, 8

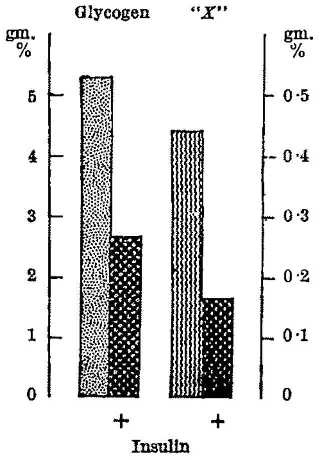

Fig. 2. Effect on liver glycogen and glucosyl oligosaccharides of subcutaneously injected insulin. Six rats maintained on an *ad libitum* diet were killed as controls for six other rats which were killed 2 hr. after receiving the insulin

Thus, in three different sets of physiological circumstances (starvation, glucose feeding, insulin administration), hepatic glucosyl oligosaccharides fluctuated in the same direction as did liver glycogen.

The possibility of artefacts due to the isolation is unlikely inasmuch as the glucosyl oligosaccharides can be separated from liver by simple physical means (centrifugation, dialysis) and since no oligosaccharides result from glycogen which has been subjected to the isolation process[1].

The possibility was also considered that oligosaccharides were produced from glycogen by amylase in blood contaminating the liver homogenate. The duration of this action would be the interval separating removal of the liver to the deproteinization of the homogenate.

In this connexion, it was first shown that rat-liver supernatant does not produce detectable amounts of oligosaccharides from glycogen or starch in the time interval referred to above. Thus, 2 gm. of fresh rat liver were homogenized in 15 ml. of ice-cold distilled water and centrifuged at high speed in a refrigerated centrifuge for 30 min. The supernatant was tested for amylase activity using two substrates, starch and glycogen. The soluble starch (1 per cent) was made up in phosphate buffer *p*H 6·9 according to Bernfeld[5] and the glycogen (1 per cent) in 0·02 *M tris* buffer (*p*H 7·4) and 0·0067 *M* sodium chloride. The experimental digests contained 1 ml. of buffered substrate and 1 ml. of liver supernatant solution. The controls contained boiled supernatant. The digests were incubated at 20° C. for 3 min. and the reaction stopped by boiling. The addition of 0·5 ml. of 10 per cent zinc sulphate and 0·5 ml. 0·5 *N* sodium hydroxide precipitated the protein, which was filtered off. The reducing power of the filtrate was determined[6]. No increase in reducing power of the test digests versus controls was observed, signifying the absence of amylase activity under the conditions employed.

Moreover, experiments were done in which the portal vein of the liver of a nembutalized rat was perfused *in situ* with Ringer's solution to remove as much as possible of the blood trapped in the tissue. Subsequent analysis showed the presence of glucosyl oligosaccharides in amounts similar to those usually found in the unperfused liver.

Finally, it may be expected that if glycogen was undergoing amylolytic degradation in the liver homogenate then the extent of this process should progressively increase with time. This expectation was not realized. Thus, a 10 per cent rat-liver homogenate was prepared and kept at 0° C. At five different time-intervals up to 15 min., aliquots were removed and the glucosyl oligosaccharides were determined. The concentration of this material (125 mgm. per cent) was unchanged during the course of this experiment.

On the other hand, the evidence does not rule out the possibility that in the intact animal, glucosyl oligosaccharides may result from the physiological action of liver amylase. If this is the case, the extent of this process is much greater than expected and its control by the physiological influences examined here would represent facts, unemphasized hitherto if they were known at all.

It is regarded as significant that the liver contains an amylomaltase[7] which synthesizes maltotriose and maltotetraose from maltose. The role of this series of compounds is understood in the carbohydrate metabolism of plants. They function as primers in the synthesis of polysaccharide catalysed by plant phosphorylase[8–12]. On the other hand, glucosyl oligosaccharides may be intermediates in glycogen synthesis if one considers the case where a trisaccharide (not a substrate) speeded up dextran synthesis catalysed by cell-free extracts of *Aspergillus niger* by serving as a glucosyl acceptor[13].

The implication of the above findings is that glucosyl oligosaccharides (no matter what their origin) may enter somewhere into the mechanism of glycogen synthesis. In this connexion, it is of interest that Beloff-Chain[14] has observed the presence of maltose, maltotriose and maltotetraose in rat diaphragm exposed to glucose labelled with carbon-14. Synthesis of oligosaccharides and glycogen from glucose but not glucose-1-phosphate was stimulated by insulin. Certainly the findings of Beloff-Chain on rat diaphragm resemble the present observations in rat liver.

We are satisfied from the results presented that the presence of glucosyl oligosaccharides in liver homogenate is not due to artefact. The exclusion of this explanation brings us face to face with the questions of their origin and of their possible significance in the metabolism of liver glycogen. These are deserving of further experimental study.

INHIBITION AND ACTIVATION OF POLYNUCLEOTIDE PHOSPHORYLASE THROUGH THE FORMATION OF COMPLEXES BETWEEN ACRIDINE ORANGE AND POLYNUCLEOTIDES

By Dr. ROLAND F. BEERS, jun., and Dr. DANIEL D. HENDLEY

Robert W. Johnson Laboratory, Children's Hospital Inc., 3825 Greenspring Avenue, Baltimore 11, Maryland

AND

Dr. ROBERT F. STEINER

Division of Physical Biochemistry, Naval Medical Research Institute, National Naval Medical Center, Bethesda 14, Maryland

ACRIDINE orange reacts with the bases of polyadenylic acid to form a spectrophotometrically distinct complex (complex I) with an absorption peak at 465 mμ [1] (see Fig. 1). We have also discovered, however, that with an excess concentration of polymer (ratio of bases to dye 100 : 1) complex I disappears and is replaced by a second complex, II, with an absorption peak at 502 mμ associated with strong fluorescence in the green (Table 1). Treatment of polyadenylic acid with formalin, which blocks the formation of complex I [1], does not prevent the formation of complex II. The addition of magnesium reduces the concentration of complex II (see inset *B* of Fig. 1) and increases the concentration of complex I. Magnesium has no effect on the formation of complex I at nucleotide–dye mole ratios of 1 : 1 or less[1]. Low concentrations of sodium hydroxide ($3 \times 10^{-4}\,M$) abolish complex I, but do not affect complex II; high concentrations of sodium hydroxide ($3 \times 10^{-3}\,M$) abolish complex II and free the dye in its alkaline form with an absorption peak at 440 mμ. In view of the insensitivity of complex II to formalin treatment and of its sensitivity to magnesium we conclude that acridine orange can be bound by the phosphate groups of polyadenylic acid as well as by the purine bases. The affinity of the phosphate groups for the dye is considerably greater than that of the purine base. A competition exists between magnesium and acridine orange for the phosphate groups ; another competition exists between hydroxyl ions and phosphate groups for the dye, which has a *pK* of approximately 10·1.

Alkaline degradation of polyadenylic acid results in a transient increase in the amount of complex II formed with acridine orange followed by a gradual drop to zero (see inset *A* of Fig. 1). In view of the stoichiometry of the complex II reaction and the transient increase during hydrolysis, it appears likely that the dye is bound preferentially to the secondary terminal phosphates. Phosphorylysis of polyadenylic acid with polynucleotide phosphorylase shows no transient increase, but a gradual decrease in the amount of complex II formed. The former is consistent with a random splitting of the inter-nucleotide bonds ; the latter is consistent with a splitting of the terminal internucleotide bonds. These results also indicate no stereospecificity towards the 3′- or 5′-secondary phosphates.

Complexes I and II are also formed with ribonucleic acid isolated from *M. lysodeikticus*, but there is no sharp separation between the appearances of complexes I and II as the concentration of ribonucleic acid is increased. Similar observations have been made with the copolymer, polyadenylic uridylic acid. This reflects the much higher ratio of secondary phosphate groups to the adenine and cytidine bases in the low molecular weight ribonucleic acid and the low adenine content in the co-polymer.

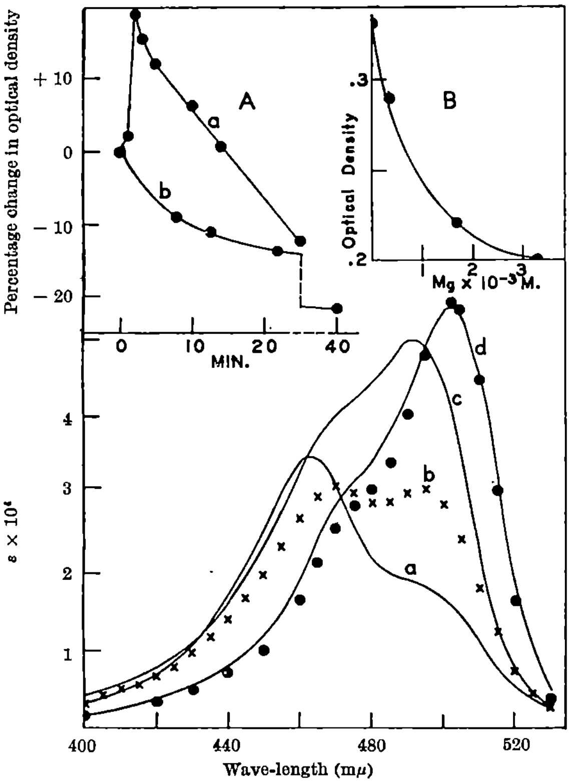

Fig. 1. Absorption curve of acridine orange (10^{-5} *M*) and its complexes at *p*H 7·0 in 0·017 *M* phosphate buffer. Curve *a*, complex I with polyadenylic acid ($1 \cdot 9 \times 10^{-5}$ *M*) ; *b*, complex I with ribonucleic acid ($7 \cdot 2 \times 10^{-5}$ *M*) ; *c*, free acridine orange ; *d*, complex II with polyadenylic acid (9×10^{-3} *M*) ; closed circles, complex II with deoxyribonucleic acid ($4 \cdot 9 \times 10^{-3}$ *M*). (Concentrations recorded as total organic phosphate.)

Inset *A* : *a*, per cent change in optical density at 500 mμ of complex II with polyadenylic acid during alkaline hydrolysis of the polymer at 100° in 3×10^{-3} *M* sodium hydroxide ; *b*, per cent change in optical density at 500 mμ of complex II with polyadenylic acid during phosphorylysis by polyase in $2 \cdot 7 \times 10^{-2}$ *M* dipotassium hydrogen phosphate, *p*H 9·0, $5 \cdot 4 \times 10^{-4}$ *M* magnesium chloride, 37°. Colour test : 0·5 ml. of polyadenylic acid solution, 0·5 ml. 0·01 *N* sodium hydroxide, 1·0 ml. water, 1 ml. $2 \cdot 91 \times 10^{-5}$ *M* acridine orange.

Inset *B* : decrease in concentration of complex II with polyadenylic acid with increasing concentrations of magnesium. Optical density recorded at 500 mμ. Reaction mixture contained 0·017 *M* phosphate buffer, *p*H 7·0, $2 \cdot 1 \times 10^{-4}$ *M* polyadenylic acid, 10^{-5} *M* acridine orange and magnesium chloride

Table 1. EFFECT OF DEOXYRIBONUCLEIC ACID (DNA) AND POLYADENYLIC ACID (POLY A) IN LARGE EXCESS UPON THE ABSORPTION SPECTRUM AND FLUORESCENCE INTENSITY OF ACRIDINE ORANGE

The solvent is 0·01 *M* sodium acetate, 0·5 *M* potassium chloride, *p*H 6·6

Dye conc. × 10^{-6} *M*	Material added	Concentration	Optical density, $\lambda = 500$ mμ	Relative fluorescence intensity, $\lambda_a = 490$ mμ $\lambda_b = 500$ mμ
3·3	none	—	0·089	1·0
3·3	poly A	$1 \cdot 41 \times 10^{-8}$ *M* (AMP units)	0·101	2·2
3·3	HCHO-poly A	$1 \cdot 41 \times 10^{-3}$ *M*	0·101	2·2
5·0	none	—	0·245	1·0
5·0	DNA	3×10^{-3} mgm./ml.	0·260	1·3
5·0	DNA	6×10^{-3} mgm./ml.	0·269	1·4
5·0	DNA	0·45 mgm./ml.	0·296	2·9

Complex II is also formed with deoxyribonucleic acid. (This excludes the 2′-hydroxyl groups of the polyribonucleotides.) The absorption spectrum of the deoxyribonucleic acid complex II is almost identical with that of polyadenylic acid. No evidence for complex I with deoxyribonucleic acid has been obtained with either native or alkaline denatured material. The green fluorescence of nuclei stained with acridine orange observed by Armstrong and Niven[2] is, no doubt, the result of the formation of complex II with deoxyribonucleic acid. The red fluorescence (phosphorescence ?) reflects the formation of a mixture of complexes I and II with ribonucleic acid. The deoxyribonucleic acid complex II is probably the same deoxyribonucleic acid-dye complex described by Peacocke and Skerrett[3] for other dyes of the acridine series. The failure of deoxyribonucleic acid to form complex I provides a potentially highly specific and sensitive method for determining deoxyribonucleic/ribonucleic acid ratios in nucleic acid mixtures. Moreover, if the nonreactivity of the 6′-amino-groups of deoxyribonucleic acid is a function of its double helical structure, then it would appear likely that ribonucleic acid is a single helix.

Alkaline hydrolysis of ribonucleic acid abolishes its ability to form complexes I and II. Boiling deoxyribonucleic acid in 0·05 *N* sodium hydroxide for 1 hr. has no effect on its ability to form complex II. Adenosine 5′-phosphate and adenosine diphosphate at concentrations of 10^{-3} *M* do not form complex II with acridine orange. The proteins, lysozyme and albumin, do not form complexes I or II. Methylene blue forms analogous complexes I and II with the respective absorption peaks at 600 and 670 mμ. Complex II is not sensitive to alkali, reflecting the fact that methylene blue does not possess a *pK* in the alkaline region.

The rate of synthesis and phosphorylysis of polyadenylic acid by polyase is inhibited by acridine orange. This can be reversed by increasing the concentration of magnesium (Table 2), even under conditions in which magnesium itself becomes progressively inhibitory. The curve of the rate of polymerization versus adenosine diphosphate concentration has a slope independent of the concentration

Table 2. EFFECT OF CONCENTRATION OF MAGNESIUM ON THE INHIBITION BY ACRIDINE ORANGE OF THE RATE OF SYNTHESIS OF POLYADENYLIC ACID

of acridine orange. Thus a fixed drop in the polymerization-rate occurs which is independent of the substrate concentration (Table 3). Nevertheless, the per cent inhibition decreases with increasing substrate concentration. A similar relationship exists between the rate of phosphorylysis of polyadenylic acid and its concentration (Table 4). However, there are both relative and absolute decreases in inhibition by acridine orange.

These findings indicate that acridine orange inhibits by forming a complex with the polymer, presumably complex II. The constant drop in the rate of polymerization in the presence of acridine orange is consistent with the previous conclusion[4] that the rate-determining parameter in the polymerization process is the concentration of the polymer molecules, of which a fixed quantity is removed for a given concentration of acridine orange. Moreover, these results also appear to show that this enzyme system is able to synthesize additional polymer molecules, the concentration of which is proportional to the initial concentration of adenosine diphosphate. Further evidence for this has been obtained by observing an increase in the concentration of complex II formed during the polymerization process with increasing concentrations of adenosine diphosphate or enzyme and with time. At low ionic strength the inhibition by acridine orange of polymerization can be reversed by the addition of polyadenylic acid. A similar effect is observed with the contaminating ribonucleic acid of the enzyme preparations.

Under conditions in which the quantity of ribonucleic acid contamination of the reaction mixture is low and the ionic strength relatively high, varying the concentration of salt, which has been found to vary the Michaelis constant[5,6], has no effect on the per cent inhibition by the dye but does cause an absolute change in the rate of polymerization (Table 5). This indicates that ionic strength influences the polymerization reaction but does not affect the rate or extent of synthesis of primer. Other studies have shown that increasing potassium chloride concentrations strongly activate the rate of phosphorylysis of polyadenylic acid by polyase[7]. Thus far, no evidence of a disproportionation between the rate of polymerization and phosphorylysis of polyadenylic acid has been obtained with various purified fractions of the enzyme, which would suggest the presence of a primer synthesizing enzyme in addition to a polymerizing enzyme[7,8].

The above picture is complicated by the finding that at low concentrations of potassium chloride and acridine orange the dye can increase the polymerization-rate more than 100 per cent. The addition of magnesium enhances the activation by the dye. Increasing the substrate concentration decreases the relative extent of activation but does not appear to reverse it. At fixed concentrations of acridine orange increasing concentrations of ribonucleic acid in the polymerization reaction mixture cause a marked decrease in the inhibition by the dye, followed by a marked activation. These findings suggest that the activation by the dye may occur through the formation of complex I. It is possible that the activation process involves neutralization of the internucleotide phosphates by the bound dye. A similar result is obtained from the shielding effect of high concentrations of potassium chloride.

Preliminary studies of the effect of acridine orange on the growth of *M. lysodeikticus* in submerged cultures[9] at *p*H 8·5 show that the extent of inhibition of growth by a given concentration of the dye depends upon the size of the inoculum. In one experiment 10^{-7} *M* acridine orange inhibited the extent of growth of a 24-hr. culture 40 per cent. A concentration of 1·4 × 10^{-4} *M* magnesium chloride completely overcame this inhibition. It would appear, therefore, that at sublethal concentrations of the dye the mechanism of inhibition of growth is through the formation of complex II. The biological role of polyase may, therefore, be implicated.

Preparation of Block and Graft Copolymers in Systems where the Life-time of the Kinetic Chain is Long

We have reported[1] that block copolymers may be prepared by adding methyl methacrylate to a latex of polyvinyl acetate prepared by gamma-irradiation of the monomer emulsion. Polymer radicals trapped in latex particles initiate polymerization of the second monomer, forming linear block copolymer molecules.

It is apparent, however, that more copolymer is formed than can be accounted for by this mechanism. Latexes prepared from 1 gm. of vinyl acetate containing of the order of 10^{16} latex particles should, following the arguments of Smith and Ewart[2] that half the particles contain live radicals, give a yield of block copolymer of approximately 2 mgm. In fact these latices have been found to yield 0·05–0·10 gm. of copolymer per gram of vinyl acetate together with large excesses of methyl methacrylate polymer.

During the polymerization of the second monomer no further radicals are generated, the propagating radicals remain trapped in the latex particles and so mutual termination reactions do not occur. The kinetic chain-length is thus essentially limited only by the amount of methyl methacrylate added. The molecular weight of the polymer molecules is, of course, limited by chain transfer reactions. During the course of the polymerization of a gram of methyl methacrylate by 10^{16} radicals, transfer to monomer and polymer must occur many times. Transfer to monomer will account for the pure polymethyl methacrylate found in the system. Transfer to polyvinyl acetate will lead to branched graft copolymer molecules which must form the preponderant part of the copolymer yield.

Transfer-limited molecules may also be obtained by adding styrene emulsions to previously irradiated polymethyl methacrylate films. Small amounts of block copolymer are found in the film, but the bulk of the polymerization occurs in the supernatant styrene emulsion. The characteristics are essentially similar to a true emulsion polymerization. The rate is given by $k_p n[M]$, where k_p is the propagation constant for styrene, $[M]$ the monomer concentration and n varies between the number of latex particles formed and half that number. The temperature increment of the rate is 7·2 kcal., which is close to the energy of activation of propagation for polystyrene. The molecular weight of the polystyrene is exceptionally high, measurements of viscosity indicating a range of $4–12 \times 10^6$. The samples of higher molecular weight have high Huggins constants[3] and are probably highly branched.

Our suggestion is that polymerization proceeds in the polymer film until such time as transfer to monomer occurs and the resulting small radicals escape into the supernatant phase and initiate emulsion polymerization of styrene. The size of the polystyrene formed is, to a large extent, limited only by transfer. The measured molecular weights are in fact in excess of the limit to the number average set by the monomer transfer constant, but a dead polymer molecule can resume growth as a branched molecule if another radical is transferred to it.

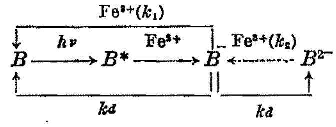
Photo-reduction of Methylene Blue and Thionine by Ferrous Sulphate using Flash Irradiation

When dilute solutions of methylene blue in 0·1 N sulphuric acid are subjected to flash photolysis with orange-red light in the presence of ferrous sulphate ($\sim$ 0·1 M), the kinetic curves obtained by monitoring at various wave-lengths can all be interpreted in terms of the following reaction scheme:



By direct measurement, the rate constant (k_d) for the dismutation of the semiquinone radical (B^-) was found to be of the order $1·5 \times 10^9$ l. mole^{-1} sec.$^{-1}$. By observing the degree to which the formation of leuco methylene blue (B^{2-}) was suppressed by the addition of ferric iron, the value of k_1/k_d and hence k_1 ($\sim 2·4 \times 10^5$ l. mole^{-1} sec.$^{-1}$) was obtained. The latter is so much smaller than k_d that the quantity of ferric iron produced by the photochemical reaction has no appreciable effect on the dismutation of the semiquinone radical.

The reverse of the dismutation reaction, if sufficiently rapid, would lead to an appreciable equilibrium concentration of semiquinone in partly reduced methylene blue solutions. This would allow of two routes for the re-oxidation of the leuco-base, namely, by direct reaction with ferric iron, or by reaction of ferric iron with the equilibrium concentration of semiquinone. Rough observations of the rate of re-oxidation, taken in conjunction with the above value for k_1, suggest that the equilibrium concentration of semiquinone must be very much less than the value reported by Michaelis and co-workers[1] for dilute acid solutions.

In view of the observations of Bridge and Porter[2,3], it is of particular interest to determine whether the semiquinone in the present experiments is produced via the triplet state or by direct reaction of the excited singlet state. This point has been investigated with thionine, the behaviour of which on flash photolysis is qualitatively similar to that of methylene blue. If the semiquinones were formed solely by reaction of the excited singlet states of the dyestuffs, the quenching of fluorescence by ferrous sulphate should be related to the yield of semiquinone by the expression:

$$\frac{\varphi_\infty}{\varphi} = 1 + \frac{1}{K[\mathrm{Fe}^{2+}]}$$

where φ_∞ refers to the yield of semiquinone in the presence of a large excess of ferrous iron, and K is the normal Stern–Volmer fluorescence quenching constant (K is of the order 1 l. mole^{-1} for thionine under the conditions of experiment). With thionine the above relationship is not obeyed. The yield of thionine semiquinone rises to 50 per cent of its maximum value within the range $[Fe^{2+}] = 10^{-3}$–10^{-2} M, where the stationary concentration of triplet is decreasing rapidly. Since 50 per cent quenching of fluorescence is only reached at $[Fe^{2+}]$ in the region of 1 M, it appears that direct reaction of the singlet excited state is very small at the lower concentrations of ferrous iron, and in the latter region therefore the semiquinone must originate from some other source, presumably the triplet state. It is possible that the semiquinone is formed from the excited singlet state also, at the high concentrations of ferrous iron required to quench fluorescence.

The work with thionine and methylene blue is being continued and will be reported in detail elsewhere.

Spectrophotometric Determination of Protein in Alkaline Solution

This method for the spectrophotometric determination of protein in alkaline solution was developed in order to determine the protein of *Chlorella* cells. It was not possible to obtain *Chlorella*-cell protein, readily, in acid solution. It was possible to break most of the cells by grinding mechanically with silica sand but this method is tedious and time-consuming. The latter point is important when it is necessary to measure physiological changes which proceed at a rapid rate.

Total protein was measured by the Folin phenol reagent[1] with a Zeiss spectrophotometer (Type *PMQ*II). All compounds which contain peptide bonds give a colour reaction and are measured by this method, but the actual figures obtained were based on total nitrogen as determined by the Kjeldahl technique. Kjeldahl nitrogen was converted to protein by using the usual factor of 6·25 (ref. 2).

The reagents used in the spectrophotometric method were:

(*A*) 2 per cent sodium carbonate in 0·1 N sodium hydroxide.

(*B*) 0·5 per cent crystalline copper sulphate ($CuSO_4.5H_2O$) in 1 per cent sodium or potassium tartrate (which was freshly prepared because complex salts were precipitated after standing for about an hour).

(*C*) Alkaline copper solution (1 ml. of reagent *B* was mixed with 50 ml. of reagent *A*. This solution was discarded after one day).

(*D*) Folin reagent diluted with water, 1 : 1 (this is the phenol reagent of Folin and Ciocalteu, manufactured by Bayer, West Germany).

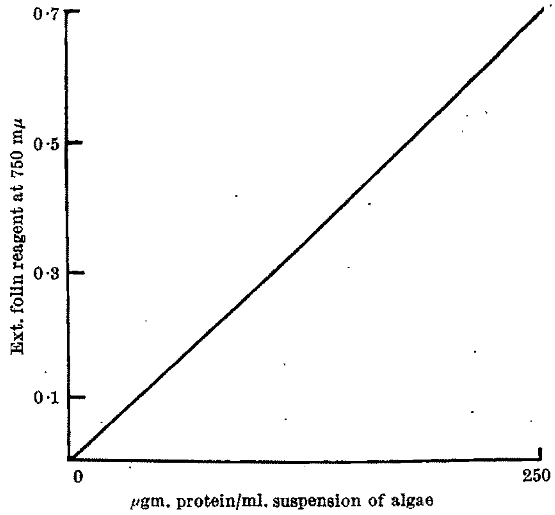

Fig. 1. Calibration curve

The experimental procedure was as follows: 5 ml. of an algal suspension was placed in a 15-ml. centrifuge. The cells were centrifuged, washed, 5 ml. of 1 N sodium hydroxide was added and the whole placed in a boiling water-bath for 10 min. (It was found that on boiling for longer periods of time there was no significant increase or decrease in the protein extracted.) The contents of the tube were centrifuged and the sodium hydroxide extract added to 5 ml. of water. The diluted extract was thoroughly mixed and 1 ml. taken and added to 5 ml. of reagent *C* and allowed to stand for 10 min. 0·5 ml. of the diluted Folin–Ciocalteu reagent was mixed with this solution and after 40 min. the extinction of the solution was measured at 750 mμ. A control blank was always used and the results were calculated as μgm. protein per ml. of algal suspension from the calibration curve (Fig. 1). With duplicate samples the error was within 5 per cent.

This work was carried out at the University of Marburg, West Germany.

Spectrophotometric Determination of Total Carbohydrate

The colour reaction given by anthrone reagent was used for the determination of carbohydrates by a spectrophotometric method. The method used is based on those of Fales[1] and Schlegel[2] but was considerably modified. For example, Schlegel used a wave-length of 570 mμ in order to correct for the presence of pigments in the plant material. But in the technique described here, a blank containing only the plant material (for each determination) and sulphuric acid were used. It was therefore possible to measure the carbohydrate content of the plant material (in this case *Chlorella* cells) at different

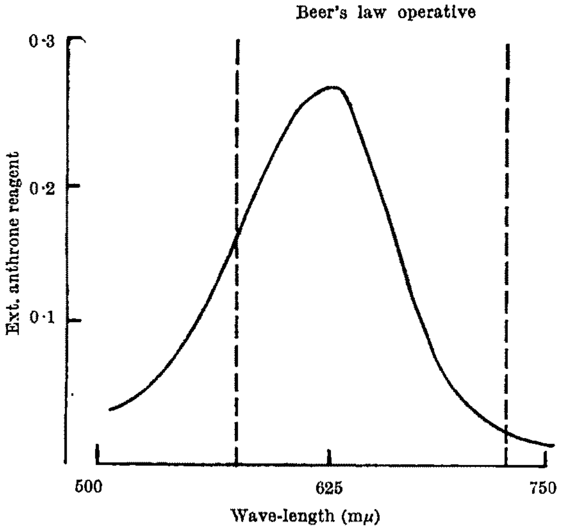

Fig. 1. Extinction of anthrone reagent

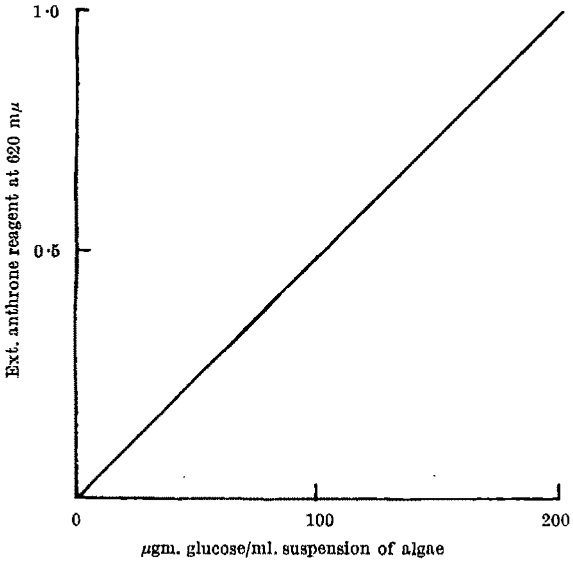

Fig. 2. Calibration curve

stages of growth and when the cells contained different amounts of chlorophyll. Nevertheless, a small but constant error, due to the colour of the anthrone reagent itself, is always present.

The reagent consisted of 0·2 gm. anthrone, 8 ml. absolute alcohol, 30 ml. water, and 100 ml. concentrated sulphuric acid (specific gravity 1·84).

A small volume of algal suspension was diluted five times and to 1 ml. of this suspension 10 ml. of anthrone reagent was added. This was then placed in a boiling water-bath for 7 min. and cooled immediately afterwards. The extinction was measured at 620 mμ (Fig. 1) and the amount of total carbohydrate expressed in μgm. glucose per ml. suspension by using a calibration curve (Fig. 2). A high ratio of reagent to suspension (10 : 1) was necessary because lower ratios did not give a straight-line relationship. The error involved in duplicate samples was less than 8 per cent. This work was carried out at the University of Marburg, West Germany.

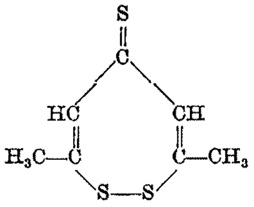
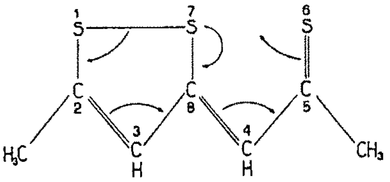
Thio-Thiophthen : an Unusual New Type of Aromatic System

In the present communication we report our preliminary findings in researches on a series of sulphurated cyclic compounds, carried out jointly with G. Traverso of the Physical Chemistry Institute of the University of Pavia.

Arndt *et al.*[1] gave formula I for a compound obtained by treating diacetyl-acetone in benzene solution with phosphorus pentasulphide. From X-ray analysis, we have deduced formula II.



I



II

This structure is characterized by no-bond resonance, which confers an aromatic character on the two rings in full agreement with the properties of the substance[2]. We propose to name this condensed ring system 'thio-thiophthen'.

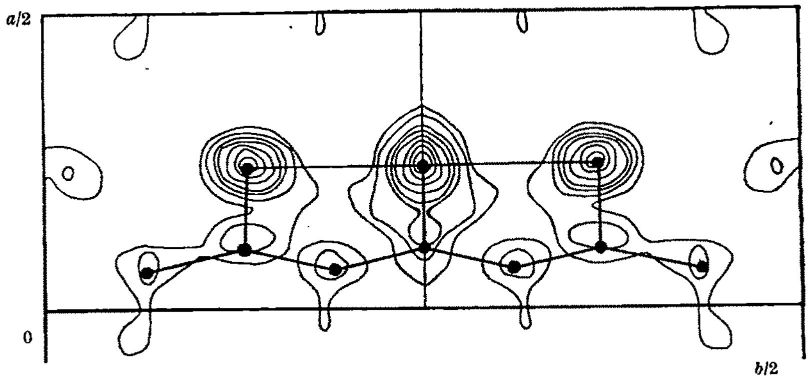


Fig. 1. First electron density projection on (001) : Sayre's equation gave 43 on 68 terms. The indicated positions of atoms are from the first Fourier summation allowing for all structure factors

The substance, prepared by G. Traverso, was crystallized from *tert.* butyl alcohol as thin rectangular or rhomboidal plates. Single-crystal precession and Weissenberg photographs showed an orthorhombic system, space group *Pnma*, with *a*, 7·80; *b*, 20·10; *c*, 5·36 A. and 4 molecules in the unit cell. Observed density, 1·47; calculated, 1·48. Tests of centrosymmetry[3,4] were used to exclude space group $Pna2_1$. Four molecules in the space group *Pnma* require the central sulphur atom and the C_8 atom to be in a special position on the mirror plane at $y = 1/4$.

Every attempt to make the Arndt structure (I) agree with our experimental results, by means of Patterson and Fourier analysis, gave negative results. We succeeded, however, with methods which did not make any assumption about the configuration of the molecule.

Using the Sayre–Cochran–Penfold method[5] we were able to fix the position of atoms, with a reliability index $R = 0·29$ for *hk*0 reflexions and 0·41 for reflexions 0*kl*.

Luzzati's error-curve[6] has confirmed these results, indicating a mean error in the co-ordinates of about 0·10 A. in the first case, and 0·08 A. in the second. Further, the Buerger 'minimum function' method[7] gave maps which agree fully with the previous ones.

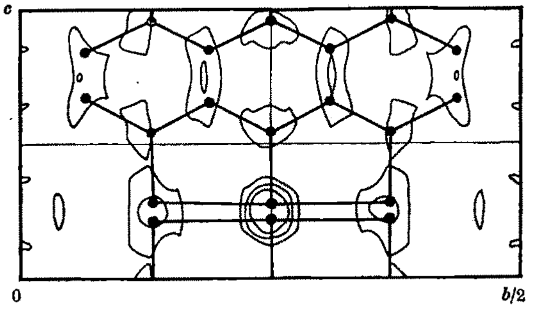

Fig. 2. Buerger's map of the minimum function M_4 (*yz*) on (100). The indicated positions of atoms are from the first Fourier summation allowing for all structure factors

In Figs. 1 and 2 respectively electron-density maps for the plane (001), calculated by Sayre's equation, and for plane (100), obtained by the Buerger method, are shown.

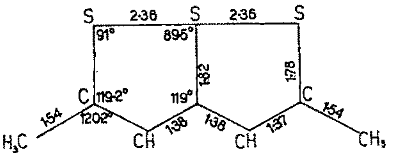

Fig. 3

The molecular shape, shown in Figs. 1 and 2, and the interatomic distances and angles indicated in Fig. 3, are the results of two successive Fourier syntheses, allowing for all structure factors. At the present stage the molecule appears to be quite planar; the C—S distances are less certain than the others. Bond-lengths of 1·37–1·38 A. between the five carbon atoms of the rings characterize the aromaticity of the nucleus. Since the distance between sulphur atoms is 2·36 A., while in compounds of the type[8] *R*—S—S—*R* it is 2·04 A., the S—S bond order is less than unity. The linear system S—S—S is also interesting in relation to the transition state of nucleophilic substitutions to sulphur[9].

The Electron Affinity of Atomic Oxygen

In a recent communication, Morris and Schmeising[1] applied the empirical extrapolation of ionization potentials of isoelectronic ions to determine the binding energy of the O^- ion (the atomic oxygen electron affinity). By extending the order of the extrapolation through eight isoelectronic ions (to S^{7+}), they find a slightly higher value, 1·044 eV., than is found from the more usual quadratic extrapolation. Stating that experimental determinations of the electron affinity have given results in unresolved conflict, Morris and Schmeising refer to three discordant values. A value of about 2·2 eV. was obtained by a thermodynamic evaluation of the probability of attachment of electrons to atomic oxygen at a hot filament, and from electron impact studies undertaken originally to determine the dissociation energies of molecular nitrogen and carbon monoxide. The value of 1·48 eV. is given by the optical threshold for photodetachment from O^- by Smith and Branscomb. The value of 1·05 eV., which coincides with Morris and Schmeising's extrapolation, was obtained by Schüler and Bingel from the analysis of a certain discrete band spectrum thought to be due to a transition between two bound states of OH^-. (For the original references see Morris and Schmeising[1].) My purpose here is to resolve these apparent ambiguities.

The electron impact experiments referred to by Morris and Schmeising are not now in general in conflict with the photo-detachment value, providing the correct values of the relevant dissociation energies are used in their interpretation. Hagstrum has re-interpreted[2] his results to show the good quality of the agreement. The most precise values for *EA*(O) from electron impact experiments are from the appearance potentials of zero-energy ion pairs in nitric oxide by Clarke[3] (1·47 ± 0·05 eV.) and in carbon monoxide by Lagergren[4] (1·42 ± 0·05 eV.).

The low value of *EA*(O) obtained by Schüler and Bingel depended on the analysis of a band spectrum thought to be due to OH^-. Afterwards, Barrow and Downie[5] produced evidence that the spectrum was due to neutral OH. Schüler and Michel[6] later found an ultra-violet system involving a state in common with their visible system, and both its analysis and excitation potential prove that the two systems belong to the neutral molecule. The observations of Schüler *et al.* have, therefore, no relevance to the properties of O^-.

The photo-detachment experiments on O⁻ have recently been improved[7], with the result that the optical threshold at 8460 ± 30 A. for the transition $O^- \; ^2P_{1/2} \rightarrow O \; ^3P_2 + e$ corresponds to a physical electron affinity of 1·465 ± 0·005 eV., or 33·80 ± 0·12 kcal./mol. The observations of the spectrum are direct and its interpretation unambiguous.

Since the submission of the reply by Morris and Schmeising to these comments, I have re-examined the results of Metlay and Kimball (which gave 2·3 eV. from attachment at a hot filament) in an effort to explain the remaining discordant experimental value for *EA*(O). Metlay and Kimball obtained their result from the solution of Saha's equation for *EA*(O) at each of a number of fixed values of pressure (of nitrous oxide) and temperature (of the tungsten filament). They assumed that O⁻ from the nitrous oxide was the ion which produced the measured current of negative ions. However, if one deduces the affinity of the ion (whatever it may have been) from the reciprocal dependence on temperature (at fixed pressure) of the logarithm of the ratio of currents of electrons and negative ions, one obtains straight-line plots the slopes of which give 3·7–3·8 eV. An impurity with an affinity of 3·7 eV. need only have had a fractional concentration of 6×10^{-4} in the nitrous oxide for the value of 2·3 eV. to have been obtained. The influence on this dependence on temperature of the O⁻ ions (with an affinity of 1·465 eV.) would be entirely negligible. The possibility that the nitrous oxide was contaminated with 0·06 per cent chlorine is suggested by (*a*) the value of the affinity obtained from the dependence on temperature, (*b*) the fact that Metlay and Kimball used 98 per cent pure commercial nitrous oxide purified by distillation, and (*c*) the common commercial processes for production of nitrous oxide generate small quantities of chlorine not easily removed by fractional distillation because of the similar boiling points of the two gases. This suggestion requires experimental proof by mass spectrometry, but it is evident that the data of Metlay and Kimball are internally consistent only if one supposes that the ion observed had a large affinity and small concentration.

The empirical extrapolation methods for finding electron affinities have recently been reviewed[8]. It was found that, of these methods, extrapolation through an isoelectronic sequence of the first excited configuration, proposed by Bates, is the most successful for the elements from boron to fluorine and aluminium to chlorine. However, none of the methods rests on any real theoretical justification for extension from neutral atoms and positive ions, the valence electrons of which move in coulomb fields, to negative ions, where these fields are of short range. Furthermore, the empirical extrapolations are most useful for interpolating the affinities of aluminium, silicon and phosphorus, by arbitrarily adjusting the predictions to agree with the known affinities of carbon, oxygen, fluorine, sulphur and chlorine, for each extrapolation method gives results in error by about 0·5 eV. for these ions. For example, the Glockler extrapolation, used by Morris and Schmeising, when applied to fluorine and chlorine gives 2·93 and 3·05 eV., respectively, and this result is almost independent of the order of the extrapolation. But these values are about 0·7 eV. lower than the known affinities of these gases. If one adds 0·7 eV. to the oxygen affinity predicted by the Glockler extrapolation in quadratic form (that is, interpolating *EA*(O) from fluorine and chlorine) one finds 1·4 eV., in reasonable agreement with the photodetachment results (1·465 eV.). However, the same correction applied to the quadratic Glockler extrapolation for sulphur 'corrects' the affinity from 2·07 eV. to 2·8 eV., while the photodetachment value for *EA*(S) is, by coincidence, just 2·07 eV. Furthermore, Geltman[8] has shown that for some atoms the predictions of the Glockler method are strongly dependent on the order of the extrapolation, and the nature of this dependence varies radically from element to element. Thus, since the extrapolation methods rest on an uncertain theoretical basis, the answer to the question which method is best may require experimental values for so many of the ions that the value of empirical methods for prediction is greatly reduced.

[8] Branscomb, L. M., "Negative Ions" in "Advances in Electronics and Electron Physics", **9** (Academic Press, New York, 1957).

Branscomb has provided further results in support of a figure of about 1·465 eV. for the first electron affinity of atomic oxygen $E(O \rightarrow O^-)$, and there is strong evidence for this value. However, the difference between this result and the value of Metlay and Kimball[1], $E(O \rightarrow O^-) = 2{\cdot}33$ eV., obtained from electron attachment at a hot filament, still has to be accounted for. In addition, various extrapolation methods[2] give rather lower values than 1·465 eV. for the first electron affinity of oxygen. For example, the extrapolation procedure used by us yielded $E(O \rightarrow O^-) = 1{\cdot}044$ eV., and it seems appropriate to make some comments on this procedure.

The technique employed by us is a development of that due to Glockler[3] and assumes that the ionization potentials *I* of isoelectronic ions satisfy a function f(*Z*) of the atomic number *Z* which is continuous and well behaved. A major disadvantage of the procedure is that the results essentially represent very small differences between large numbers, and they may therefore be subject to considerable uncertainty if the ionization potential data utilized are not accurate. In our application of the method to the case of the electron affinities of oxygen, there was some doubt as to the values of some of the ionization potentials, and the electron affinity values obtained appeared to be the most probable on the basis of the original premise.

To test the general validity of the extrapolation procedure it is applied here to the estimation of the electron affinity of atomic hydrogen, the value of which is known with high accuracy from quantum-mechanical calculations[4]. In this case the requisite ionization potentials for the estimation are known with high precision. The values quoted by Moore[5]

Table 1. IONIZATION POTENTIALS OF IONS ISOELECTRONIC WITH H–

Z	Ion	Ionization potential (I) Moore	Selected value
2	He	24·580	24·580
3	Li^+	75·6193 ± 0·0031	75·6193
4	Be^{2+}	153·850 ± 0·012	153·850
5	B^{3+}	259·298 ± 0·025	259·298
6	C^{4+}	391·986 ± 0·037	391·986
7	N^{5+}	551·925 ± 0·062	551·9336
8	O^{6+}	739·114 ± 0·074	739·157

are listed in col. 3 of Table 1 together with their probable errors. If the data in col. 3 are extrapolated to $Z = 1$, the result for the electron affinity of hydrogen $E(H \rightarrow H^-) = 0{\cdot}7198$ eV. is obtained. However, a difference table shows some 'noise' which may be removed by smoothing the second differences somewhat. Working both ways from the column of smoothed second differences, one can obtain the data listed in col. 4 of Table 1, and extrapolation yields $E(H \rightarrow H^-) = 0{\cdot}7092$ eV. This is in excellent agreement with the value of about 0·71–0·75 eV. obtained by quantum-mechanical calculations. This agreement shows that the premise concerning $f(Z)$ is correct in this case.

Oxidized Iodine in Sea Water

IN *Nature* of August 3, 1957, p. 250, T. I. Shaw and L. H. N. Cooper suggested that the oxidized form of iodine in sea water is, in all probability, hypoiodous acid and is not iodate, as we believed[1]. We were interested in the reasons for their conclusion; but we cannot accept their view.

First, of three different reactions which determine theoretically the equilibrium of the system (I_2, I^-, IO^- and IO_3^-) in oxygenated sea water:

$$I_2 + OH^- \rightarrow I^- + IO^- + H^+ \quad (a)$$

$$3IO^- \rightarrow 2I^- + IO_3^- \quad (b)$$

$$I^- + \tfrac{1}{2}O_2 \rightarrow IO^- \quad (c)$$

they dismiss reaction (*b*) on the arbitrary assumption that the reaction may be slow because it is trimolecular; then they calculate the ratio hypoiodite/iodide to be unity.

Our experiments have shown that the reaction in question goes smoothly in the given conditions, whereas reaction (*c*) goes on with great difficulty, and, in practice, it can be ignored. Furthermore, experimentally we have reached the conclusion that there is no probability of hypoiodite being detected in sea water.

Table 1

Sample	Phenol added (ml.)	Sodium hydroxide added (ml.)	Iodide-iodine found (μgm. at./l.)	Oxidized-iodine found (μgm. at./l.)
1	0	0	0·15	0·21
2	3	0·5	0·15	0·21
3	6	1·0	0·15	0·21

Our experiments may be summarized as follows:

(*A*) Three different 200-ml. samples of the same sea water were treated with various amounts of 5 per cent phenol solution and 3 N sodium hydroxide solution, and were processed according to our method of iodine determination[2]. If the original sea water had contained hypoiodite, it would have been decomposed by the phenol treatment, giving a smaller value for the oxidized iodine[3]. The results in Table 1 show that, contrary to Shaw and Cooper, the oxidized iodine was not in the state of hypoiodite.

(*B*) 1 litre of a sea water sample was put in a stoppered bottle with iodine and shaken for 1 hr. (1) 20 ml. of the solution thus obtained was titrated with 1/500 N thiosulphate solution. The titre, which corresponds to free iodine and the hypoiodite formed from it, was 4·5 ml. Then the solution was acidified with 3 ml. of 3 N hydrochloric acid. Iodine was liberated and consumed an additional 1·0 ml. of the thiosulphate solution, which corresponds to iodate originating in hypoiodite. (2) Another 20-ml. portion of the solution was acidified and titrated; the thiosulphate solution consumed was 5·5 ml. (3) After the addition of potassium iodide, another 20-ml. portion was treated as in (2), and this required 5·5 ml. thiosulphate. (4) To another 20 ml., 2 ml. of a 5 per cent phenol solution was added: the orange colour of the solution disappeared. After 3 min. the solution was acidified with hydrochloric acid and the solution became tinged with yellow, pointing to the liberation of iodine, which consumed 1·0 ml. of the thiosulphate solution. It is evident that hypoiodite directly, and free iodine indirectly via hypoiodite, were removed by phenol, leaving untouched the iodate which first liberated iodine by acidification. (5) Another 20 ml. was treated with phenol and sodium hydroxide solution; this required 1·0 ml. of thiosulphate solution. (6) Portions were treated as in (1) after lapses of 1–25 days. With time, the amount of thiosulphate solution required for the first titration gradually decreases, with a corresponding increase in that required for the second titration. This shows that the velocity of reaction $3IO^- \rightarrow 2I^- + IO_3^-$ is high (see Fig. 1).

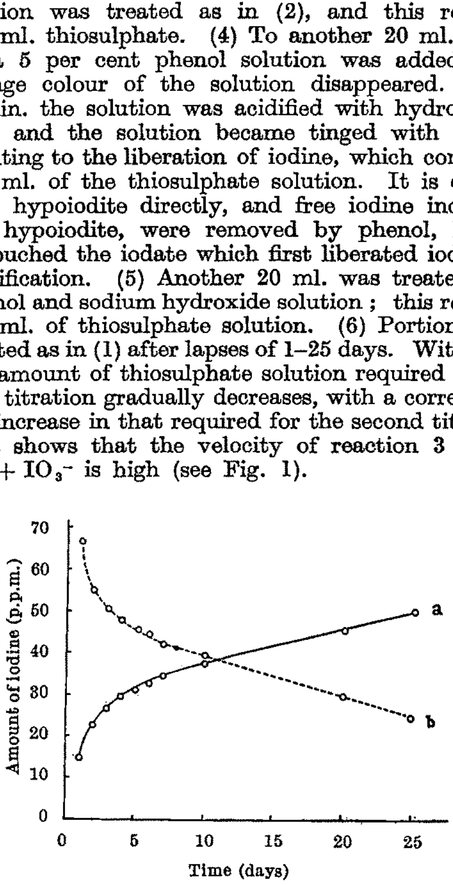

Fig. 1. (*a*) Iodate curve; (*b*) hypoiodite curve

Summarizing the experimental results: (1) there is no detectable amount of hypoiodite in sea water; (2) the system iodine, iodide, hypoiodite and iodate reaches a thermodynamical equilibrium rather quickly with iodide and iodate ions as predominant components; (3) even in the presence of oxygen, the oxidation of iodide to a higher oxidized state does not occur easily; otherwise iodate would be only one possible state of iodine in an oxygenated sea water. For reasons (2) and (3), iodine in sea water remains in practice in two states, namely, iodide and iodate.

Shaw and Cooper's view that the ratio of hypoiodite to iodide is unity is thus untenable: as a matter of fact, even if the values are limited to those of the off-shore waters of Honshu[1a], to which they refer, the ratio varies from 0·88 to 1·75 with an average of 1·43, a value which cannot be easily made unity in round figures when the accuracy of determination is taken into consideration. Furthermore, among our later results from other regions[1b], which were apparently not available to them when formulating their views, we find many extreme values such as, for example, those for the 0 m. sample from station Satsuma 29, lat. 03° 38′ N., long. 141° 56′ E., 0·00 μgm. atom iodate-iodine/litre and 0·06 μgm. atom iodide-iodine/litre with iodate-iodine/iodide-iodine = 0·00, while for the 0 m. sample from station Satsuma 5, lat. 13° 54′ N. and long. 150° 57′ E., iodate-iodine and iodide-iodine are respectively 0·21 μgm. atom/litre and 0·04 μgm. atom/litre, with the ratio iodate-iodine/iodide-iodine equal to 5·2.

[3] Li, C. H., and White, C. F., *J. Amer. Chem. Soc.*, 65, 335 (1943).

WINKLER[1] has demonstrated that a substantial part of the iodine naturally present in sea water is in an oxidized form which he considered to be iodate. I have suggested that the bactericidal nature of sea water towards coliforms is due to the presence of this iodate[2].

Shaw and Cooper[3] have recently published a communication on the mechanism of iodine oxidation in sea water in which they demonstrate thermodynamically that aerial oxidation of iodide would take place at the *p*H of sea water. They recognize that the thermodynamically stable form of oxidized iodine at this *p*H is iodate, but on the grounds of the third-order kinetics of the hypoiodite–iodate conversion, and the presence of biological activity, claim that iodate would not be formed. They consider that the oxidized form of iodine present would be an equilibrium mixture of iodine and hypoiodous acid (hypoiodite).

My work on the coast of New Zealand is not in agreement with these views, as the experimental evidence indicates that the oxidized form of iodine present in the local sea water is iodate, with no evidence for the presence of a detectable amount of hypoiodite. This experimental evidence is briefly as follows.

(*a*) Upon the addition of excess iodide to local sea water, a formation of the triiodide ion is not observed spectrophotometrically at 356 mμ, or by the formation of a blue colour with starch, unless the solution is, in each instance, first acidified. If, as according to Shaw and Cooper, the iodine was present as hypoiodite, then the above reactions would have been given without acidification. Solutions of iodate of equivalent concentrations to that found in sea water react only when acidified.

(*b*) When the amount of oxidized iodine is estimated as above, the concentration of oxidizing material found is too great to be other than iodate. In my earlier paper I showed that the amount of oxidizing material was equivalent to 150 μgm./litre of iodine, that is, the amount of iodate which would be formed from 25 μgm./litre of iodine, which is in agreement with the observations of Winkler[1] and others[4]. If this amount of oxidizing substance were hypoiodous acid or hypoiodite, then it would need to have been formed from 75 μgm./litre of iodine, which is more than is usually regarded as being present.

In the light of the above evidence I consider that the local sea water contains iodate. Sulphamic acid was used for the acidifications as it effectively prevents interference from nitrite.

J. K. JOHANNESSON

[1] Winkler, L. W., *Z. angew. Chem.*, 29 (1), 205 (*Brit. Chem. Abs.*, A, ii, 389; 1916).

[2] Johannesson, J. K., *Nature*, 180, 285 (1957).

[3] Shaw, T. I., and Cooper, L. H. N., *Nature*, 180, 250 (1957).

[4] Harvey, H. W., "The Chemistry and Fertility of Sea Waters" (Cambridge Univ. Press, 1955).

TAKEN together, Sugawara and Terada's experiment *A* and Johannesson's evidence form more cogent reasons for believing iodate to be the oxidized form of iodine in the sea than the reasons we presented for believing hypoiodous acid to be the oxidized form. However, as we indicated, the volatility of iodine from sea water seems to demand that a large part of the iodine should be in the form of hypoiodite. Unless the volatility can be explained quantitatively in terms of an iodate–iodide mixture, the state of iodine in the sea cannot be considered as satisfactorily settled.

Moreover, we find that whereas Sugawara and Terada's conclusions upon the rate of oxidation of iodide in the sea are doubtful, their conclusions upon iodide–iodate–hypoiodite equilibration have slender experimental foundation.

First, if iodide oxidation in the sea were as slow as Sugawara and Terada's laboratory experiment—and one that we have made—suggest, then we should expect that turbulent mixing would prevent variations in the amount of oxidized iodine between neighbouring portions of sea water. Sugawara[1], however, has presented results showing that the amount of oxidized iodine varies between samples taken simultaneously at the same station but differing in depth by only a few metres. He finds, for example, at the surface on station 1 a total concentration of iodine of 41·3 μgm./litre and a concentration of iodide of 15·8 μgm./litre, whereas at 10 m. the total iodine is 41·4 μgm./litre but the iodide 18·0 μgm./litre. The lowest value for the eddy diffusion coefficient in Kuroshio water is given[2] as 7 gm. cm.$^{-1}$ sec.$^{-1}$; whence, in the absence of known biological accumulators of iodate, it would appear that, to achieve or maintain this difference, at least some 7 per cent of the iodide in the sea there undergoes oxidation daily while a somewhat similar fraction of the oxidized form undergoes reduction. To attribute the variations solely to rapid reductive processes would be unsound, since these would lead to iodide being the sole marine form of iodine.

Secondly, in experiment *B*, where Sugawara and Terada followed the time course of the conversion of 'hypoiodite' to iodate, it was not obvious to us whether the progressive slowing of the reaction was due to an approach to equilibrium or whether it represented solely the kinetics of the forward reaction. If equilibrium is being approached, then a back reaction of iodate and iodide should occur and give hypoiodite with accompanying iodine. To examine this we have added to filtered sea water a mixture of potassium iodide and iodate (molecular ratio 5 : 1) to give a total iodine concentration of 5×10^{-4} gm. atoms/litre. One sample was kept in the light, another in the dark. After 13 days, starch solution was added; but no blue colour developed, although a test showed that $0{\cdot}08 \times 10^{-4}$ gm. atoms/l. (1 p.p.m.) iodine would have been detectable. It seems clear, therefore, that the back reaction is negligible and that Sugawara and Terada's results represent solely the forward kinetics of iodate formation. Thus their second summarizing statement is without experimental foundation. We note that their results indicate a second- or higher-order reaction with respect to 'hypoiodite'—and if even second-order kinetics persist to the thousand-fold greater dilution at which iodine occurs naturally in sea water, then not more than 1–2 per cent of 'hypoiodite' would be dismuted to give iodate annually.

If the several observations are sound and to be reconciled, it seems that there remains to be uncovered some unrecognized process or compound involving iodine at concentrations of about 10^{-7} *M* in sea water.

Are Tektites Extra-Solar-System Meteorites?

RECENT communications to *Nature*[1] indicate that the origin of tektites is still a mystery. New evidence supporting an extra-terrestrial origin has been obtained by Ehmann and me[2]; we have found radionuclides induced by cosmic rays (aluminium-26 and beryllium-10) in some tektites (australites and Libyan Desert silica-glass) at levels comparable to those observed in stone meteorites and considerably above any conceivable levels of production by cosmic or terrestrial radiations at or beneath the Earth's surface. This finding practically eliminates not only the Earth, but also the Moon, as the source of tektites, since the bulk of lunar material expelled in collisions of giant meteorites with the Moon[1] would undoubtedly originate at depths of at least several metres, where the cosmic radiation would be negligible in intensity. Although these findings require confirmation and more adequate controls, it will be assumed in the following that tektites are glass meteorites from outside the terrestrial system.

The best defined fields of tektites range in size from approximately 53 km. × 130 km. for the Libyan Desert silica-glass to about 2,000 km. × 3,000 km. for the australites[3]. These areas are much greater than those occupied by the fragments of meteorites forming meteorite showers, indicating that the tektites of a given occurrence cannot be fragments of a single meteoroid which was shattered in the Earth's atmosphere. They must, then, have arrived at the Earth as a loose cluster of glassy objects.

On the other hand, in all known cases of loose clusters of small objects in the solar system (disrupted comets, meteor showers), dispersal through much greater distances than the Earth's diameter occurs in times of the order of one period or less. Urey[4] first emphasized the impossibility that self-gravitation could hold together for any appreciable time, against the disrupting influence of the Sun's gravitational field, clusters of such low density as would be necessary according to the meteoritic interpretation of tektites.

The hypothesis that the tektites have arrived as clusters of objects from outside the solar system provides a way out of these difficulties. Thus, the clusters would not have had to survive the local disruptive forces for long, and they could easily escape the regions of greatest gravitational-field gradients close to the Sun and major planets. Such a cluster of solid objects travelling through interstellar space would have collapsed into a small volume with the individuals touching one another, and a limited exposure to the disruptive forces experienced upon arrival in the solar system may explain the low density of the cluster on arrival at the Earth. The Earth's own gravitational field may be significant or even sufficient in this respect.

Using available data[3] to estimate the probable mass before fall in an individual tektite occurrence, it can be calculated roughly that, if tightly packed, about one-quarter would be strongly irradiated by cosmic rays, another one-fifth would receive moderate irradiation, and the rest would be effectively shielded. The extent of exposure would be even greater if the aggregate were loosely packed and irregular in shape. Thus an appreciable fraction of the objects should contain significant levels of induced radioactivities at the time of fall. Moreover, there should be variations in level of activity from specimen to specimen and probably regional variations over the tektite fields, so that experimental testing of the compact-cluster hypothesis is possible.

An extra-solar-system origin of tektites may also be subject to experimental verification, through isotopic analysis of the constituent elements. In view of the apparently widespread occurrence in the universe of synthesis or modification of elements, of the apparent variety of processes participating in this activity, and of the apparently continuing level of such activity[5], it is quite likely that matter formed elsewhere than our own may have different isotopic composition of some or many of its elements. Even if the processes were the same, if the times were different there would be differences in the abundances of the shorter-lived primary natural radionuclides (especially uranium-235 and potassium-40); and some extra-solar-system matter should contain locally extinct radionuclides of shorter life-time (such as curium-247, plutonium-244, uranium-236, lead-205, samarium-146, iodine-129, etc.).

H. Suess[6], from considerations similar to the above (though not regarding the tektites to be of different origin from the meteorites in general), measured the specific potassium-40 radioactivity of potassium from several tektites and meteorites. None of the samples differed significantly from terrestrial potassium, leading to the presumption that the elements in tektites and meteorites were formed by the same mechanism and at the same time as those of the Earth. However, the measurements were of low precision and gave no information on the ratio of stable isotopes. Altogether, very little is known about the isotopic composition of the elements in tektites, which may constitute our first and only accessible samples of matter from outside the solar system. Burbidge *et al.*[5] point out the decisive importance for problems of stellar nucleogenesis of information on the isotopic composition of elements from other parts of the universe.

A non-solar-system nature of tektites would lessen the difficulty of explaining their failure to fit into the system comprising the recognized types of meteorites. Moreover, it opens for speculation (and experimental testing) a wide variety of possible origins not possible under the restrictive assumption that they are members of the solar system.

Behaviour of the Present Sunspot Cycle

THIS communication deals with the sunspot numbers during the years 1944–57, and gives a forecast for the years 1958 and 1959. It is part of a research on the behaviour of sunspots since 1863 that will be published in due course.

Monthly and annual averages of sunspot numbers have no heliophysical meaning, because the month and the year have nothing to do with the Sun. The only acceptable average is that based upon the solar rotation with its synodical period of 27·2753 days (see, for example, Nautical Almanac, 1958). It must be remarked, however, that this figure is not as accurate as is suggested by the four decimal places, since the Sun's rotation is variable, depending upon the heliographic latitude. This value has, however, been adopted in order to link the present results with this average solar rotation. For the whole period from 1899 to March 1958, running 27·275-day averages have been calculated, in such a way that the difference between the calculated day and the theoretical one never exceeded one day.

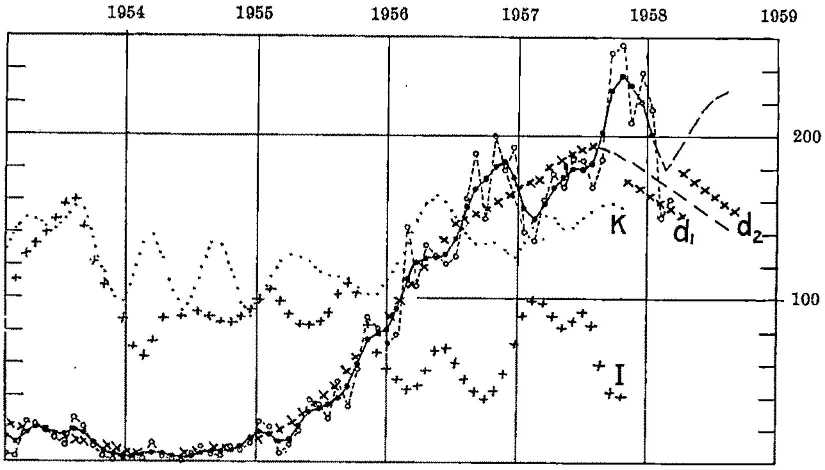

Fig. 1

Waldmeier's method of smoothing through 13 months (applied for the first time by Wolf in 1872) is not adequate, 13 months being too long. In the present investigation the smoothing method $(R_1 + 2R_2 + R_3) : 4$ has been applied. In this way a new row of figures is obtained and the same procedure may be applied again and so on. Hence smoothed rows based upon 4, 5 and more original figures are obtained. This has been continued with up to five original R's, which gives quite acceptable results. These are represented by the formula:

$$R_m = (R_1 + 4R_2 + 6R_3 + 4R_4 + R_5) : 16$$

If the values obtained are compared with those of Waldmeier the advantages of the method used are obvious.

Figs. 1 and 2 contain the following curves: *a*, the average value of R for each rotation of the Sun, at the first day of the rotation; *b*, the smoothed curve R_m; *c*, the smoothed monthly values of Waldmeier; d_1 and d_2, two of Waldmeier's predictions, for October 1957 and March 1958; *K*, the smoothed magnetic character figures after Bartels for Witteveen (Netherlands); *I*, the smoothed ionospheric index for De Bilt (Netherlands).

The curve *b* shows an outstanding series of secondary waves, especially in the neighbourhood of the sunspot maxima. This feature is common to all sunspot cycles investigated hitherto. The amplitudes are large enough to be statistically significant. The curve *c*, Waldmeier's smoothed curve, is obviously inaccurate; its secondary waves, 1948–50, are definitely opposite to those of curve *b*, a feature obvious in all sunspot cycles investigated. This behaviour is caused by the factor mentioned above: the epoch of Waldmeier's extremes is strongly influenced by the long interval of 13 months. Waldmeier has especially emphasized a secondary maximum of 148·5 in October 1948. It coincides with a

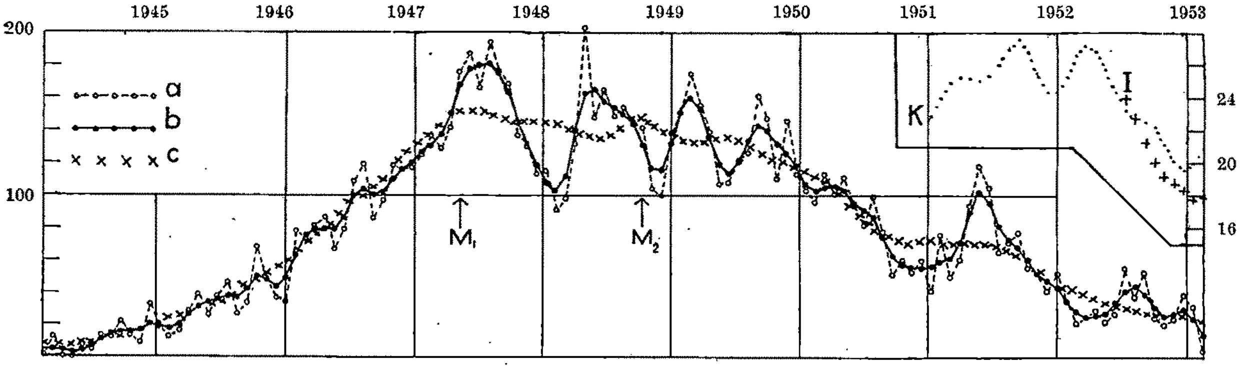

Fig. 2

minimum in the new curve. His high value is caused by the two secondary peaks on both sides.

Each month Waldmeier gives a prediction of his smoothed values of R for the coming half year. Two of these predictions have been plotted in Fig. 1 (d_1 and d_2). His maximum was in August 1957, with a smoothed value of 193·9. Without violating his curve it may be continued just between his two rows of predicted points.

The maximum of the new curve was reached in October 1957. The first secondary maximum may be expected about June to August 1958. A minimum in the rotational average was reached in March 1958 ; the sunspots then rose again, passing 300 at the end of March. The second secondary maximum must follow in the first half of 1959. It should be emphasized, however, that neither the heights nor the epochs of these maxima can be fixed exactly.

As regards the magnetic character, K, and the ionospheric index, I, calculated in the same way as the curve b, their course is fairly independent of the sunspot curve. During the whole of the rapid rise of the sunspot curve in 1957 both K and I were pretty well constant. Apparently both phenomena depend upon the occurrence of solar eruptions which do not by any means run parallel to the sunspots.

Direct Measurement of the Velocity of Propagation of a Ferromagnetic Domain Boundary in 'Perminvar'

MEASUREMENTS of the velocity of propagation of a ferromagnetic domain boundary were first carried out in the well-known experiment of Sixtus and Tonks[1]. Afterwards, Williams *et al.*[2] were able to measure the velocity of a single domain wall observed to exist in a [100] 'picture frame' single crystal of 3·5 per cent silicon-iron. These measurements were later extended to ferrite single crystals[3] and to polycrystalline 65 per cent nickel–iron made pseudo-single crystalline by annealing in a magnetic field[4].

All these measurements are indirect in so far as they are obtained by applying a sudden change in field and recording the value of dB/dt from the e.m.f. induced in a secondary coil. The wall velocity is then determined from the observed maximum value of the dB/dt pulse (or its integrated value) and the domain geometry as observed under static conditions by Bitter patterns.

Using a modification of the Kerr magneto-optic effect described by us[5], we have succeeded in measuring directly the velocity of the domain wall in magnetically annealed 'Perminvar' (composition, per cent : nickel 45, iron 30, cobalt 25) kindly supplied by the Post Office Research Station, Dollis Hill, London, in the form of an annular ring 1 in. external and 3/16 in. internal diameter and 147 microns thick. Observations using the Kerr effect showed that a large part of the total change in magnetization took place by radial movement of a single circular wall from the inside edge outwards. The modification of the original apparatus consists simply in using a double slit instead of a single slit as the source of illumination, focused so as to give on the surface of the specimen a light probe consisting of two rectangular images separated by a distance of 1·45 mm. The reflected light was received by a photomultiplier after transmission through a single-layer 'Polaroid'. The light intensity incident upon the photocathode then changes suddenly as the wall moves across the two images forming the light probe, and the photomultiplier output is observed on an oscilloscope as a double step. Using single-sweep operation with a calibrated time-base, the oscilloscope traces were photographed and the time taken for the wall to pass across the light probe was calculated. Fig. 1 shows a typical output trace.

A complete set of measurements in which the velocity of the wall ranges from 0·2 to 80 cm./sec. is shown in Fig. 2. For small driving fields the velocity obeys the relation :

$$V = G(H - H_c)$$

in which H_c is a critical field-strength necessary to maintain movement of the domain wall. H_c was

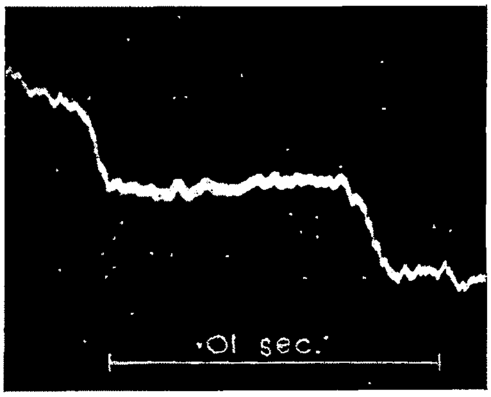

Fig. 1

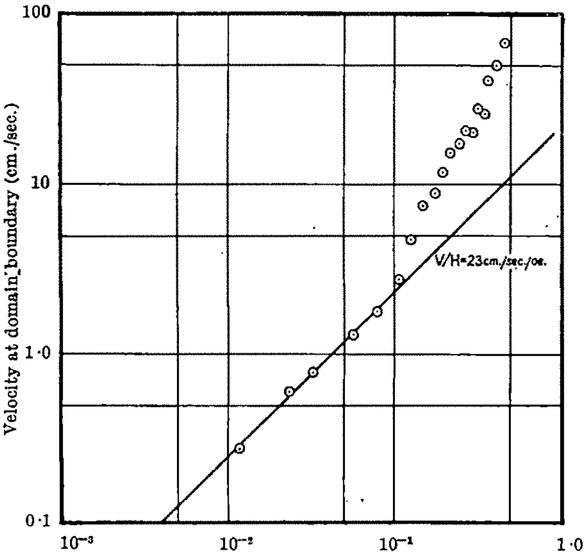

Fig. 2. Velocity of the domain boundary as a function of the excess field. The value of the excess field decreases from the inside of the specimen outwards, and H is the field at a point midway between the double light probe. The measurements are not corrected for this variation of the field

found to be 0·108 oersted. In the theoretical approximation in which the wall remains plane and relaxation effects are ignored:

$$G = \frac{\pi\rho F}{128 I_s d}$$

in which I_s is the spontaneous magnetization, ρ the electrical resistivity, d the thickness of the specimen and F is a numerical factor equal to 1·06 for a specimen of the dimensions used here. Taking $I_s = 1{,}200$ gauss, $\rho = 1{\cdot}86 \times 10^4$ e.m.u., the calculated value of G is 27 cm./sec./oersted, which agrees well with the measured initial slope of the V *vs.* $(H - H_c)$ curve, namely, 23 cm./sec./oersted. The very small discrepancy between these two values, which may be due to the neglect of relaxation effects, indicates that the velocity of the domain wall is limited almost entirely by eddy currents.

It is proposed to extend these experiments, and a fuller account will be given later.

Aluminium Nitride Precipitates in α-Iron

AN investigation which we have carried out provides more detailed information concerning the morphology of aluminium nitride precipitates formed in an α-iron matrix than that recently reported by Hsiao[1].

We employed a vacuum-melted alloy containing 1 per cent aluminium (ingot U of the Sloman and Evans aluminium deoxidation series[2]) made by adding 1 per cent of aluminium and 0·5 per cent of oxygen to iron of composition:

Carbon	0·0045 per cent	Phosphorus	0·004 per cent
Silicon	0·002 ,,	Nickel	0·001 ,,
Manganese	0·002 ,,	Copper	0·012 ,,
Sulphur	0·0048 ,,	Magnesium	0·0005 ,,

It was nitrided in dry ammonia gas for 5 hr. at 640° C. and cooled in the furnace. This treatment produced a nitrogen concentration gradient which extended inwards from the surface of the specimen for about 0·035 in. Examination by optical microscope of the inner portion of the nitrided zone showed a poorly resolved, mottled structure. (Any areas that contained colonies of finely dispersed aluminium oxide inclusions were avoided during the examination.)

Using the single etch extraction replica technique[3], precipitates were isolated from the nitrided zone in dry-stripped 'Formvar' replicas after etching the specimen for 3 min. with 10 per cent 'Nital' and examined by electron microscopy. The innermost portion of this zone contained two types of precipitate, namely, (*a*) long, narrow rods about 0·05μ across and up to about 4μ in length, and (*b*) small angular particles up to about 0·1μ across (Fig. 1). The method of selected area transmission electron diffraction available with a Metropolitan-Vickers type *EM*3 electron microscope enabled patterns to be recorded from each type separately. In both

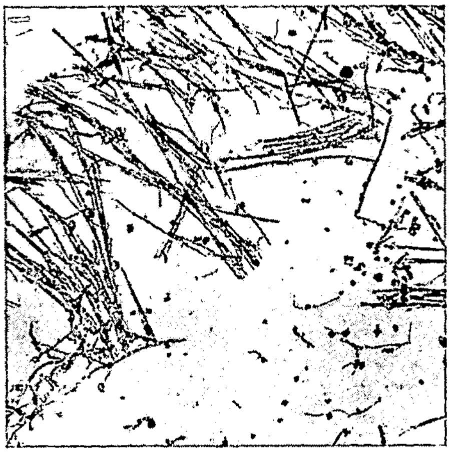

Fig. 1. Rod-like and angular aluminium nitride precipitates isolated from a nitrided iron – 1 per cent aluminium alloy in a 'Formvar' extraction replica. Electron micrograph, × 8,000

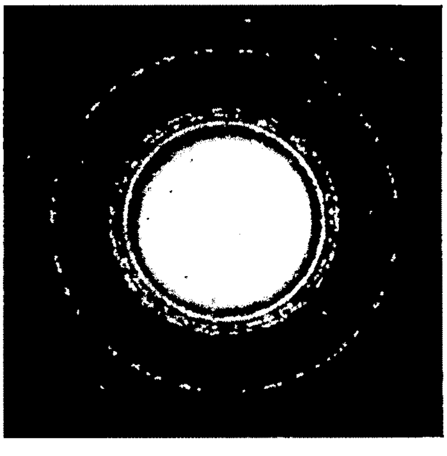

Fig. 2. Aluminium nitride transmission electron diffraction pattern obtained from both types of precipitate shown in Fig. 1

* ASTM X-ray Data Card No. 3-1144.

instances, the full aluminium nitride (AlN) pattern was obtained (Fig. 2 and Table 1). No additional lines were present.

A similar examination of areas within the mottled zone nearer the surface, and therefore having a higher nitrogen content, revealed a dense array of rod-like precipitates, finer than those shown in Fig. 1, that again gave electron diffraction patterns wholly characteristic of aluminium nitride. No angular particles were present.

These observations suggest that rod-like particles are the characteristic form of precipitation of aluminium nitride in an α-iron matrix. Unless there is interference from other elements present, this is also likely to be the characteristic form of aluminium nitride occurring in steels.

Hsiao[1] has isolated small particles up to 0·08μ across in a 'Formvar' replica dry-stripped from a nitrided steel containing 0·035 per cent aluminium after etching the specimen surface for about 15 sec. with 1 per cent 'Nital', and has assumed them to be aluminium nitride. Although they appear somewhat similar to the type (*b*) aluminium nitride precipitates of Fig. 1, other considerations suggest that they may not have been correctly identified. Thus, neither the rod-like nor the angular form of the aluminium nitride precipitates isolated from the nitrided iron – 1 per cent aluminium alloy exhibited signs of attack after severe etching with 'Nital', whereas Hsiao[1] has reported that many of the particles reputed to be aluminium nitride were dissolved during the mild 'Nital' etch given to effect isolation. The uncertainty associated with Hsiao's identification of the extracted particles could, however, be resolved if transmission electron diffraction studies were made directly on the particles in the extraction replica instead of inferring their identity from reflexion electron diffraction studies made on the etched metal section.

The information given above relating to the morphology of aluminium nitride precipitates was briefly reported at the annual conference of the Electron Microscopy Group of the Institute of Physics held at Bangor in September 1957. A fuller account of the work is to appear elsewhere. Thanks are due to Mr. R. A. Hacking, director of research, for permission to publish this communication.

Formation of Prostaglandin *in vitro*

THE contracting power of smooth muscle in seminal fluid and in extracts from prostatic and vesicular glands was described independently by von Euler[1] and Goldblatt[2]. The biological and chemical characteristics were further studied by von Euler[3]. The active principle, prostaglandin, was shown to be an organic, unsaturated acid without nitrogen. *In vivo* and *in vitro* it produced an increased tone and motility in many smooth muscle organs, for example, in the uterus and the intestine. Highly purified preparations of prostaglandin have a contracting effect on smooth muscle of isolated duodenums of rabbits comparable with that of acetylcholine[4]. The active principle has hitherto been found only in secretions and extracts from the prostatic and vesicular glands from man and sheep. More recently, other naturally occurring substances with similar biological and chemical characteristics have been described[5].

In the present series of experiments the active principle is extracted from organs or seminal fluids with two volumes of acidified acetone (1 ml. 3 N hydrochloric acid per 100 ml. acetone). After evaporation of the acetone under reduced pressure, the active factor is extracted from the aqueous phase by shaking thoroughly with ethyl acetate at a *p*H less than 3. The factor is then extracted by shaking vigorously with 0·15 M phosphate buffer at a *p*H greater than 7·5.

Biological assay was performed on the isolated, atropinized duodenums of rabbits in a 15 ml. organ-bath. The Tyrode solution was aerated with 6·5 per cent carbon dioxide in oxygen. Most of the preparations were also tested by rabbit's blood pressure. One unit per litre of bath fluid gives a definite effect on the isolated duodenum of the rabbit. Prostatic glands from man and vesicular glands from sheep contain about 3–5 units prostaglandin per gm. of organ. Seminal fluid, however, contains 30–50 units prostaglandin per ml. In the first experiments seminal fluid was left standing at room temperature; this caused no change in the content of prostaglandin. In a second series of experiments the vesicular glands from sheep were homogenized in two volumes (v/w) of 0·15 M phosphate buffer at *p*H 7·15. The homogenate was incubated at 38° C. with continuous shaking for varying periods. The reaction was stopped by adding two volumes (v/v) of acidified acetone and the active factor was then extracted as above. In these experiments 1 gm. of organ yielded up to 50 units prostaglandin (Fig. 1).

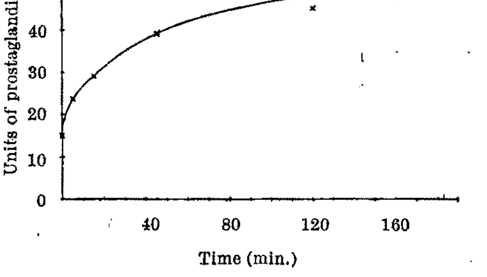

Fig. 1. Vesicular gland from sheep. Homogenized and incubated in 0·15 M phosphate buffer at *p*H 7·15. Temperature, 38° C.

Vogt[6] has shown that when lecithin from egg yolk is incubated with lecithinase *A*, a fatty acid, with a contracting action on smooth muscle resembling that of prostaglandin, is split off from the lecithin molecule. Francioli[7] has demonstrated lecithinases in prostatic glands of different species. The effect of lecithinase *A* on the formation of prostaglandin *in vitro* was therefore tested.

As source of the enzyme, venom from *Naja naja* (cobra) was used. 10 μgm. of venom per ml. buffer in an incubation experiment similar to that described above increased the formation of prostaglandin (Table 1).

It is known that the histamine liberator 48/80 releases not only histamine but also a slowly reacting substance[8]. When 48/80 was used in the prostaglandin experiments, however, it definitely inhibited the formation of prostaglandin (Table 1).

Table 1. EFFECT OF INCUBATION ON PROSTAGLANDIN CONTENT OF VESICULAR GLAND OF SHEEP. ORGANS HOMOGENIZED AND INCUBATED AT 38° C. IN 0·15 *M* PHOSPHATE BUFFER AT *p*H 7·15

Substances added	Units of prostaglandin per gm. gland		
	Non-incubated	Incubated 1 hr.	Incubated 2 hr.
Without addition	2·5	25	40
Cobra venom, 10 μgm./ml.		60	80
48/80, 10 μgm./ml.		15	20

Thus prostaglandin can be liberated from the vesicular gland of sheep in amounts which correspond to that found in seminal plasma. This formation can be enhanced by lecithinase *A*, and inhibited by 48/80. The reactions involved in the formation of prostaglandin are under investigation and will be published elsewhere.

Potassium Atractylate, a New Inhibitor of the Tricarboxylic Acid Cycle

THE roots of *Atractylis gummifera*, a Mediterranean member of the Compositae called "masticogna" in Sicily and "musciurida" in Sardinia, contain potassium atractylate, which is a glycoside the aglycone of which is not yet chemically known though it can be obtained in crystalline form[1].

The pharmacological properties of the roots of *Atractylis gummifera*, called *Camaeleon niger*, were well known in classical times and are referred to in Dioscorides' "De Materia Medica". These therapeutic properties have been almost completely forgotten, however[2]. We have recently been engaged in testing the pharmacological activity of potassium atractylate[3].

In the present communication the results of investigations carried out in animals are summarized. Potassium atractylate injected into mice, rats, rabbits and dogs at first causes hyperglycæmia (until the reserves of glycogen in the liver and muscles are exhausted), then hypoglycæmia with typical convulsions, acidosis (probably by increasing the concentration of lactic acid in the blood), and diminished oxygen consumption.

The sensitivity of the animals to the toxic action of the drug undergoes seasonal variations; thus 5 mgm./kgm. body-weight injected intravenously is sufficient in winter to kill a dog, whereas in summer a dose 4–5 times larger is necessary.

Convulsions disappear after administration of glucose, but the animals die in a state of deep depression, even after administration of bicarbonate in order to prevent acidosis. Thus, the metabolic block seems to be irreversible. The resynthesis of the glycogen of liver and muscles is inhibited, whereas the glycogen content of the heart is either not modified or is even increased.

Potassium atractylate seems to act at the level of the tissues, since it diminishes the oxygen consumption and inhibits the synthesis of glycogen by the isolated rat diaphragm and since oxidation of liver homogenate is inhibited by very low concentrations (3·5 × 10^{-6} *M*) of the drug. It is probable that potassium atractylate inhibits selectively the tricarboxylic acid cycle as it reduces the oxygen consumption of the isolated mitochondria at the same rate as it does in the homogenate. A strong inhibition of the synthesis of adenosine triphosphate has also been demonstrated directly by chromatographic determination.

It seems to be important to point out that the rate of oxidation of pyruvic and ketoglutaric acids is more depressed than that of oxalacetic acid, and that the uptake of phosphate is much more depressed than might be expected from the corresponding depression of oxygen consumption (in the oxidation of ketoglutarate in the presence of potassium atractylate the ratio phosphorus/oxygen is 0·86).

It seems likely that in the inhibition of the tricarboxylic acid cycle by atractylate, the systems regulating oxidative decarboxylation and phosphorylation are particularly involved.

Intracellular Changes in Levels of Polarographically Active Sulphydryl Groups in Rat Liver during Carcinogenesis

THE relationship of SH- and SS-groups to growth processes has been the subject of much research[1]. An increase in the concentration of SH-groups was usually associated with the mechanism of mitosis[2]. Since the observations of Hammett[3] and Voegtlin[4] the relatively high rate of cell division in tumours has been reported to be connected with greater amounts of glutathione in malignant tissue. Measurements

Table 1. Polarographic Test for Reduced Glutathione in Homogenized Liver during Carcinogenesis

These results refer to height (cm.) of polarographic anodic wave ($2GSH \rightarrow GSSG + H_2$) as shown directly in the homogenate containing approximately 100×10^6 units of deoxyribonucleic acid (0·5 mgm./cm.^{3})*. '*LKB*-Blomgren' polarograph, type 3266, attached to Leeds Northrup automatic recorder ('Speedomax' type *G*). Sensitivity: 10 m.amp. for full deflexion of the galvanometer. 1 cm. = 66 μgm. GSH in 1 ml.

Tissue	Normal liver	Liver fed basal diet		Liver fed 3′-methyl, 4-dimethyl aminoazobenzene								Novikoff hepatoma
Time (days)		30	180	30	60	80	100	110	150	180	210	
Value (cm.)	10·8 (5 determ.)	9·9	8·4	11·9	12·0	11·0	7·0	5·4	3·8	4·0	2·56	1·84 (5 determ.)

* DNA unit = DNA content of diploid rat nucleus = 5×10^{-12} gm. 100×10^6 DNA units = $0·5 \times 10^{-3}$ gm.

by Greenstein of the glutathione content of spontaneous and transplantable hepatomas indicated values some 10 per cent and 24 per cent lower than those of normal liver on a wet-weight basis[5].

Work performed recently in this laboratory was concerned with the question whether there are any consistent changes in the level of free, non-protein, sulphydryl groups during the 200-day period needed for development of liver tumours in Sprague–Dawley rats fed with the carcinogenic azo-dye, 3′-methyl, 4-dimethyl aminoazobenzene (0·6 per cent in a basal diet poor in riboflavin). The polarographic method was chosen because it allows ready observation and recording of changes in SH-compounds. Two tests were used: anodic oxidation of reduced glutathione ($2 GSH \rightarrow GSSG + H_2$), which gives an anodic wave at a potential[6] of +0·5 V. and can be used directly in the homogenate under nitrogen[7], and, second, Brdička's catalytic increase of cathodic current which occurs in presence of cobaltous and cobaltic ions in ammoniacal solutions. In the latter test the non-protein SH- and SS-groups give this reaction only in solutions of bivalent cobalt, while the protein-bound group gives the reaction, appearing as a characteristic 'double wave', in ammoniacal solutions of both bivalent and trivalent cobalt[8].

The application of the first test has shown that there is no change in the level of free reduced glutathione in the homogenate for approximately 80 days when the results are expressed per unit of deoxyribonucleic acid (5×10^{-12} gm.). Then there occurs a rather sudden drop in the level of reduced glutathione which falls to only 20 per cent of the original in developed hepatoma and only 10 per cent in transplantable Novikoff's hepatoma of the rat (Table 1). The sudden drop in the level of reduced glutathione after 100 days seems to coincide with that critical period of carcinogenesis when the anaerobic glycolysis suddenly starts to increase[9].

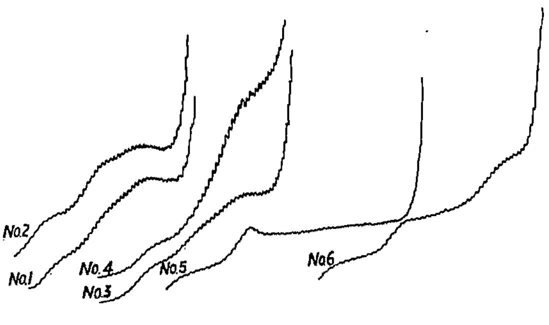

Fig. 1. Effect of the carcinogen 3′-methyl, 4-dimethyl aminoazobenzene (40 days) on free SH-groups in the supernatant of rat liver. (1) Control (basal diet) and (2) experimental, 0·2 ml. supernatant (dilution 1 : 10) added to 5 ml. Brdička's solution containing 0·1 *N* ammonium hydroxide, 0·1 *N* ammonium chloride and 5×10^{-4} *M* luteocobaltichloride. No polarographically detectable difference in sulphydryl content of undenatured soluble proteins.

(3) Control and (4) experimental, as for curves 1 and 2, but Brdička's solution contains bivalent cobalt ($CoCl_2.6H_2O$) instead of trivalent cobalt. Experimental sample shows increase of non-protein SH-groups.

(5) Control and (6) experimental. The effect in the experimental sample remains after deproteinization. Dilution by the deproteinizing agent is responsible for apparent decrease of catalytic reaction in comparison with curve 4. Sensitivity: 100 m.amp. for full deflexion

The second test was applied to the deproteinized (in an equal volume of 10 per cent sulphosalicylic acid) supernatant (1 hr. at 59,000*g*) after diluting the original homogenate to a 10 per cent suspension with sucrose. In this test a remarkable increase in the catalytic current with one single high maximum was evident in a few weeks after initiation of feeding with the carcinogenic azo-dye. This effect persisted during the whole period of carcinogenesis up to the development of gross tumours in the liver. Fig. 1 illustrates this effect in a sample prepared from liver about 40 days after the start of feeding with the carcinogen. The effect in the experimental sample disappeared if it was preincubated with 1×10^{-3} *M* iodoacetic acid for 30 min. at room temperature in slightly alkaline solution.

These polarographic observations indicate a striking change in the distribution of free SH-groups during liver carcinogenesis which may have important implications: an 'early' effect, which follows fixation of the carcinogen to protein and persists through the whole period of carcinogenesis, is manifest in the increase of sulphydryl groups; and a 'late' effect, which seems to coincide with the onset of malignant transformation and is manifest in a sudden decrease in free sulphydryl groups. Whether these effects belong to different SH-compounds or both are due to reduced glutathione in different states remains to be elucidated. It also remains to be shown whether changes in SH-levels occur in carcinogenic processes induced by other carcinogens outside the liver.

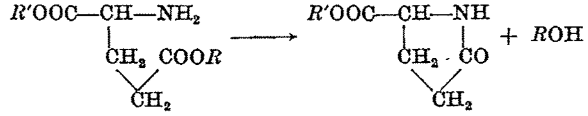
Carbon Dioxide Catalysis of the Formation of Pyroglutamic Acid

GLUTAMIC ACID and its esters and salts have a tendency to form α-pyrrolidone derivatives[1] by lactam formation :



(R,R' = H, Ca, Alkyl)

The cyclization can be brought about by heating. A strong catalytic effect of ammonia has been recorded[2].

Our experiments have revealed that carbon dioxide has a marked catalytic effect on the cyclization reaction. Dimethylglutamate is stable in dioxane at 25° C. in the absence of carbon dioxide for periods of several weeks. On saturation with carbon dioxide, however, fast cyclization occurs with a half-life of approximately 10 hr. The course of the reaction can be followed by potentiometric titration of the free amino-groups.

The reaction is of second order with respect to the amino-groups belonging to the uncyclized substance. If, however, an amine is added, which is more basic than the glutamic ester itself (for example, hexylamine), the reaction becomes of first order with respect to glutamic amine. The presence of weaker amines (for example, aniline) or tertiary amines does not change either the rate or the order of the reaction.

The order of reaction does not depend on carbon dioxide pressure, all second-order plots falling on straight lines. The dependence of the overall rate on the pressure of carbon dioxide is shown in Fig. 1. The values of k and n can be determined from the slope and intercept in the log–log plot. For dimethylglutamate at 25° C. in dioxane $n = 1{\cdot}01 \pm 0{\cdot}03$ and $k = 0{\cdot}63$ l. mole^{-1} atm.$^{-1}$ hr.$^{-1}$.

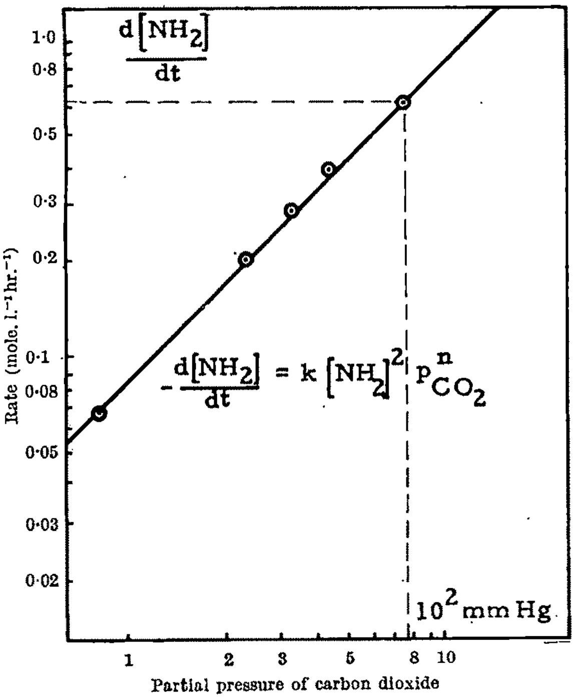


Fig. 1. The order with respect to carbon dioxide and the rate constant (k) can be determined from the plot of log(rate) vs. log(p_{CO_2}). For dimethylglutamate in dioxane at 25° C., $k = 0{\cdot}63$ l. mole^{-1} atm.$^{-1}$ hr.$^{-1}$; $n = 1{\cdot}01 \pm 0{\cdot}03$

On the basis of this evidence it can be concluded that carbon dioxide catalysed cyclization of the γ-esters of glutamic acid involves the formation of carbamates :

$$2R{-}NH_2 + CO_2 \longrightarrow R{-}NH{-}COONH_3{-}R$$

and that it is the carbamate salt which is the reactive species. (For a similar mechanism in condensations of α-amino-acids see ref. 3.) A weak base (aniline) will not be able to fix carbon dioxide.

In the series of glutamic diesters a marked influence of the nature of the γ-ester group is observed. The cyclization products of the diesters were all identified as the corresponding esters of pyroglutamic acid. The rate constants at 25° C. and 720 mm. mercury partial pressure of carbon dioxide are :

Dimethylglutamate	k = 0·600 mole.l.$^{-1}$hr.$^{-1}$
Diethylglutamate	0·280
Di-*n*-propylglutamate	0·262
Di-*iso*propylglutamate	0·038

These findings have an important bearing on the polymerization of the Leuchs anhydride of γ-esters of glutamic acid. Oligopeptides of γ-benzylglutamate in dioxane lose their amino end-groups rapidly in presence of carbon dioxide, and there is some evidence that the rate of cyclization increases with the molecular weight of the peptide. It is important to notice that during the polymerization of Leuchs anhydrides the solution is saturated with carbon dioxide, and therefore the occurrence of a termination is probable, mainly in the initial part of polymerization, when the rate of growth of the chains is low and the concentration of amino-groups is high[4]. The cyclization reaction, therefore, has an effect on the molecular-weight distribution of the resulting polymer, tending to increase the polydispersity.

Isolation of the α_2-Globulin Pattern on Starch Gel

ZONE electrophoresis of serum proteins in starch gels was first described by Smithies[1], who employed a borate buffer system and silver electrodes. Poulik[2] described a discontinuous system using *tris* (trihydroxymethylamino-methane) and borate buffers for the separation of proteins. Two-dimensional electrophoresis on paper, and then on starch gel as used by Smithies and Poulik[3,4], revealed at least six molecular size-groups in the α_2-globulin group. A modification of this method is described, which utilizes the combination of haptoglobins with hæmoglobin to give a faintly coloured band as visual marker of the α_2-region and thus avoids staining. Commercially available starch is used as supporting medium, and provides a wide separation of the individual fractions.

The first electrophoresis was carried out on a strip of Whatman paper No. 3*MM*, 14 cm. wide, applying 0·1 ml. serum over 3 cm. Approximately 0·005 ml. of a hæmoglobin solution—about 5 gm. per cent—was then added to 0·2 ml. of the same serum, and 0·1 ml. of this serum was applied to the same paper 2 cm. distant. The buffer was veronal, 0·06 *M*, and the tank was that described by Flynn and de Mayo[4,5]. Using a current of 0·2 m.amp./cm. width, the length of the run was 11·5 cm. after 17 hr. The addition of the hæmoglobin solution made the identification of the α_2-region possible without staining, because the haptoglobins of the group combined with hæmoglobin and became faintly coloured. The excess hæmoglobin superimposed on the β-globulins and the edge nearest the anode defined the limit of the α_2-region. The marked and the stained strips are compared in Fig. 1.

The starch gel was prepared from Hopkin and Williams's soluble starch (analytical reagent grade) at a concentration of 12·5 gm./100 ml. in 0·01 *M tris* adjusted to *p*H 8·5 with saturated aqueous citric acid. 10 ml. of glycerol were added to 240 ml. of buffer. The gel was poured into glass trays, 20·5 cm. × 20·5 cm., and allowed to set in the refrigerator for 30 min. The electrode compartments contained each 250 ml. 0·3 *M* borate buffer, *p*H 8·6. The wet α_2-region of the paper strip was subdivided into four strips, each 5 mm. wide, which were pressed together and inserted in the cut of a 4-cm. razor blade at a distance of 7 cm. from the cathode end. Whole serum was inserted similarly, applying 0·02 ml. to a strip of cellulose acetate, 4 cm. × 5 mm. A small amount of *tris* buffer was applied to the surface of the strips and the excess blotted off. The bridges consisted of two sections of surgical lint, 21 cm. × 10 cm., moistened with borate buffer. The voltage was applied from a power-pack giving 305 V. on load. The current started at 1·7 m.amp./cm. width and finished after 2 hr. at 2·7 m.amp. The block became perceptibly warm and was cooled for 5 min. in the refrigerator and then cut and stained as usual. Three batches—Nos. 40054, 40055 and 44874—of analytical grade of starch were employed, giving closely comparable results. Fig. 2 shows a typical electrophoresis pattern for serum and the corresponding pattern for α_2-globulins.

Substances in the Calf Alimentary Tract interfering in the Determination of Polyethylene Glycol

THE water-soluble polyethylene glycols of high molecular weight promise to be of great value as reference substances in the study of exchange processes in the alimentary canal. In particular, a mixture of such polymers with a molecular weight of about 4,000 appears to pass largely unchanged and unabsorbed through the alimentary tract in sheep, humans, hens, cows and calves[1,2]. Polyethylene glycol can readily be determined turbidimetrically, once interfering substances have been removed, after precipitation with trichloracetic acid solution containing barium chloride[2,3]. We found, in agreement with Hydén[3], that an initial treatment with barium hydroxide, zinc sulphate and barium chloride sufficed to remove interfering substances (mainly protein and sulphate) from milk and from calf rumen contents, urine and fæces extracts. The method failed, however, in two respects when it was applied to samples from fistulæ in the small intestines of milk-fed calves.

(1) The filtrates obtained from samples taken from the cæcal end of the small intestine after treatment with barium hydroxide/zinc sulphate/barium chloride contained a factor which inhibited the formation of the normal polyethylene glycol suspension on the addition of trichloracetic acid/barium chloride solution. Polyethylene glycol added to such filtrates was recovered to an extent of only 50 per cent or less. Nothing is known of the nature of the interfering substance, but it was removed on adding lead acetate to the sample made alkaline with barium hydroxide.

(2) Similar filtrates from samples obtained from fistulæ a few cm. below the junction of the abomasum and duodenum gave a strong turbidity with trichloracetic acid/barium chloride solution in the absence of polyethylene glycol. The effect was particularly marked in samples taken a few hours after feeding, and neutralization of acid in the samples with more barium hydroxide gave no improvement. The filtrate gave a pink reaction with the biuret test, and it seems probable that the interfering factor was degraded protein produced in the abomasum.

Of many metallic ion treatments tried, the only one which successfully precipitated this protein was that in which mercuric chloride was added to the sample, previously made alkaline with barium hydroxide, to give a final *p*H of about 9–10·5. At a higher final *p*H all the protein was not removed; at a lower *p*H (that is, in the presence of excess mercuric chloride) some of the polyethylene glycol was precipitated (Table 1). The mixture obtained by this procedure was difficult to filter. Moreover, the interfering factor in the contents of the cæcal end of the small intestine was not removed. Both these objections are overcome by the preliminary step in the following procedure.

Table 1

Mercuric chloride (2·7 per cent) added (ml.)	Final *p*H	Estimated polyethylene glycol in sample (p.p.m.)	
		1,000 p.p.m. polyethylene glycol added	No polyethylene glycol added
1·3	11·56	1,110	120
1·7	10·75	1,030	10
1·8	10·05	1,000	<10
2·0	9·30	1,010	<10
2·2	8·95	1,010	<10
2·6	8·60	850	<10

Sample from abomasal end of small intestine. Procedure as described in text except that different amounts of mercuric chloride were used.

The contents of the small intestine are centrifuged and 2 ml. of the supernatant fluid added to a small flask with 2 ml. water and 3 ml. of 0·3 *N* barium hydroxide. 1·5 ml. of 6·6 per cent lead acetate is added slowly and followed by 1·5 ml. of 5 per cent zinc sulphate. The mixture is filtered and 5 ml. of the slightly cloudy filtrate added to another flask with 1·5 ml. water and 1·5 ml. of 0·3 *N* barium hydroxide. To this is added, a drop at a time while shaking, 2 ml. of 2·7 per cent mercuric chloride to give a final *p*H of 9–10·5. (The concentration of the mercuric chloride solution may have to be modified slightly, depending upon the other reagents and the acidity of the samples.) The mixture is filtered, and an unknown mercuric compound which is otherwise slowly precipitated from solution is removed by the addition of one drop of 5 *N* ammonium hydroxide and a further filtration. Polyethylene glycol can be determined in the filtrate in the usual way[2]. The mean recovery of polyethylene glycol added to eleven samples from different parts of the small intestine was 101·4 per cent (standard deviation: ± 0·3 per cent).

Effect of Thyroxin Administration on the Rate and Steric Course of Enzymatic Reduction of Steroids

A necessary step in the enzymatic inactivation of Δ^4-3-ketosteroids, for example hydrocortisone, is the reduction of ring *A* [1,2]. Evidence that this process may be accelerated in thyrotoxicosis in man has been presented by Levin[3] and Peterson[4]. Because of this, the influence of thyroxin administration on the enzymatic reactions involved in the reduction was studied.

50-gm. male Sprague–Dawley rats injected daily, intraperitoneally, with 0·5 μmol. of L-thyroxin were used in the following experiments. They were killed by decapitation; livers were excised and homogenized with 2 vol. of 0·25 *M* sucrose at 0° C. Liver homogenates from rats treated as few as three days with thyroxin showed an increased ability to reduce cortisone (Table 1, col. 2). Usually little or no reducing activity was detected in liver homogenates from control rats. However, when an excess of reduced triphosphopyridine nucleotide or a system generating it was added to this incubation mixture, the results in Table 1, col. 3 were obtained. This indicated that (*a*) the rate of steroid reduction was limited by reduced triphosphopyridine nucleotide in both rat liver homogenates, and (*b*) the difference in activity between the homogenates from the thyroxin-treated and control rat was abolished by reduced triphosphopyridine nucleotide, from which one could infer the greater availability of the nucleotide for this reduction in the treated animal.

When injections were continued for a minimum of 17 days, it was found, as shown in Table 1, cols. 4 and 5, that the difference in activity could no longer be abolished by adding an excess of reduced triphosphopyridine nucleotide, and although the activities of both preparations were greatly stimulated by the added nucleotide, the homogenate from the treated animal was still approximately twice as active as the control. When the livers were fractionated by differential centrifugation[5], the increase in activity in the thyroxin-treated animal was found in the micro-

Table 1. Rate of Reduction of the 4–5 Double Bond of Cortisone by Liver Homogenates
(mμmoles cortisone reduced/min./gm. liver)

	Treated 3 days		Treated 17 days	
	Without TPNH	With TPNH	Without TPNH	With TPNH
Control	7	198	10	233
Thyroxin-treated	34	207	43	449

Liver homogenates were incubated at 37° in air with cortisone, with and without a reduced triphosphopyridine nucleotide-generating system composed of excess triphosphopyridine nucleotide, isocitric acid, isocitric acid dehydrogenase and magnesium chloride. Aliquots were removed before incubation and at 5 min., extracted with dichloromethane, the optical density of which was determined at 240 μmol. The loss of absorbance at 5 min. is expressed as μmoles cortisone metabolized/min./gm. of liver.

Table 2. Rate of Reduction of the 4–5 Double Bond of Cortisone by Cell Fractions
(mμmoles cortisone reduced/min./gm. liver)

	Control	Treated with thyroxin for 70 days
Crude homogenate	121	415
Mitochondria	6	0
Microsomes	5	174
Soluble	93	90

Experiment performed as described in Table 1 in the presence of a reduced triphosphopyridine nucleotide-generating system. Mitochondria and microsomes were prepared by a modification of the method described by Hogeboom (ref. 5). Mitochondria were washed five times and microsomes twice with 0·25 *M* sucrose. The soluble fraction was the supernatant from centrifugation of crude homogenate at 120,000*g* for 90 min.

somal fraction alone (Table 2). This increase in activity was not accompanied by an increase in the number of microsomes (judged turbidimetrically) or microsomal nitrogen.

Paper chromatography[6] of the steroids resulting from the incubation of cortisone and reduced triphosphopyridine nucleotide with microsomes from treated and untreated animals demonstrated three blue tetrazolium-reducing compounds with the mobilities of 3α- and 3β-hydroxy-5α-tetrahydrocortisone and 5α-dihydrocortisone. The reduction of Δ^4-3-ketosteroids to 5α-dihydrosteroids by microsomes and reduced triphosphopyridine nucleotide has been described by Forchielli[7]. The reaction of cortisone and reduced triphosphopyridine nucleotide with the soluble fraction obtained from treated and untreated animals produced only one blue tetrazolium-reducing compound, 3α-hydroxy-5β-tetrahydrocortisone. This has previously been described as the product of cortisone reduction catalysed by soluble enzymes of the normal rat liver[3,4].

Thus there are two effects of thyroxin on the rate of cortisone reduction : an early increase in available reduced triphosphopyridine nucleotide, and, following prolonged treatment, an increase in the activity of a microsomal enzyme catalysing the reduction of the 4–5 double bond of ring *A*. This enhanced microsomal activity results in an increase in the production of the 5α isomer. Since the soluble enzyme producing the 5β-dihydrosteroid is not affected by this treatment, there would result an increase in the ratio of the 5α to 5β isomers. This is consistent with the findings of Bradlow *et al.*[8], who reported a shift in urinary metabolites of carbon-14 testosterone from the 5β to the 5α series following the administration of triiodothyronine to humans.

The effects described here with cortisone as a substrate have also been seen with other Δ^4-3-ketosteroids (hydrocortisone, deoxycorticosterone, Δ^4-androstene-3-17-dione, testosterone, corticosterone).

Secretion of Androgens by the Adrenal Cortex of the Mouse

THE transitory inner cortical *X*-zone of the virgin female mouse first described and illustrated by Masui and Tamura[1] and later by Howard-Miller[2], Deanesly[3] and many others, regresses rapidly during the first pregnancy and only gradually in the unmated female. It is unaffected by ovariectomy. A similar zone disappears in the male mouse before maturity but persists or redevelops after immature or adult castration. In the normal male, therefore, endogenous androgens cause regression of the zone and in both the castrated male and the virgin female exogenous androgens have the same effect[4,5]. Only androgens among purified hormones do this, so it is generally agreed that male hormones must circulate in the pregnant mouse. Jones concludes[6], after a long series of investigations, that these androgens are derived from the ovaries under the stimulation of placental gonadotrophins. The present experiments show, however, that *X*-zone regression can be stimulated in the ovariectomized unmated female or in the castrated male by subcutaneous injections of adrenocorticotrophic hormone, indicating that androgens are produced by the adrenals themselves.

Eleven virgin mice ovariectomized at 20 gm. were injected either at once or a few days after the operation with Armour's 'Acthar', 4 units twice daily for 4, 5 or 10 days, and were killed on the following day, except for two mice which were killed 6 days later. Two other mice received 4 units once daily for 10 days. In these thirteen experimental animals the *X*-zone had disappeared or was in the final stages of regression in ten and in the other three it showed hyperæmia and stages characteristic of earlier degeneration. Three control ovariectomized mice had well-developed adrenal *X*-zones. Similar experiments in twelve normal virgin mice gave similar results ; in eleven the *X*-zone had regressed completely or was in the last stages of regression and in the other it had half degenerated. The reproductive organs in this group showed no indications of gonadotrophic stimulation. Out of seven normal controls the adrenal *X*-zone was intact in all except two, which showed very early stages of degeneration.

Male mice were castrated at 10 gm. and given adrenocorticotrophic hormone 4–6 weeks later when the *X*-zone was well developed, resembling the one in the virgin female. The results were similar, but rather larger or more effective doses of adrenocorticotrophic hormone were necessary for complete *X*-zone regression than in the females. Of the first seven mice receiving 5 units of adrenocorticotrophic hormone (Organon) in beeswax and oil daily for 5 days, or 8 units in gelatine daily for 5 days, only four showed partial regression of the *X*-zone. If injections of 'Acthar' (Armour) were continued for 9–10 days, however, the *X*-zone disappeared in seven of the eight mice, the remaining mouse having died on the fourth day, showing the cortical enlargement and hyperæmia which precede the degeneration of the *X*-zone. One other mouse received only 4 units daily of adrenocorticotrophic hormone (Organon) in beeswax and oil, and on the eleventh day, when it was killed, the adrenal was markedly stimulated. Not only had the *X*-zone regressed, but also in this and in four other injected mice the seminal vesicles and prostate showed tubular enlargement and glandular activity as compared with those of the castrate controls—a further indication of the presence of male hormone.

Androgens are excreted by the ovariectomized rabbit and by the pregnant ewe, monkey and cow[7]. In the monkey and cow there is evidence that they are derived from the adrenal cortex. It may be concluded that normal regression of the *X*-zone in the mouse is due to an increase in androgen secretion during pregnancy from the adrenal cortex itself such as has been found in other mammals, and is not caused by ovarian androgens, as maintained by Jones[6].

I am indebted to Dr. D. M. V. Parrott for advice on the administration of adrenocorticotrophic hormone.

Calcium and Magnesium Content of Normal Human Blood Serum

THERE is some 20 per cent difference between the mean values reported, from statistically significant numbers, for calcium, and a wide range of difference for magnesium in normal human blood serum (Table 1). It would thus appear that some, at least, of the methods currently used for the determination of these two cations in serum yield erroneous values. Indeed, until the advent of metal indicators, all so-called clinical methods for determining both calcium and magnesium were open to question.

It would appear that the ashing of whole serum is a necessary step in assessing the value of any method for determining the total calcium or magnesium in it. The literature, however, is significantly wanting in this respect, perhaps because the recovery of the metals from dry ashing procedures in silica crucibles is difficult and uncertain, and the use of platinum is precluded as it reacts with the metal indicator 'Eriochrome black *T*'. When wet-ashing methods are used, the ubiquity of calcium and magnesium makes reagent blanks a major consideration, especially with micro-methods. Hence the importance of the observation of Middleton and Stuckey[5] that tissue organic matter can be destroyed in a flat-bottomed vessel on a hot plate at about 320° C. by repeated treatment with concentrated nitric acid which can readily be distilled free from metals.

With the method already described[6] for the micro-determination of calcium and magnesium, 0·25 ml. of serum is adequate for duplicate titrations of both metals. This amount, with 0·1 ml. of nitric acid, in a small 'volumetric' shaped 'Pyrex' flask with a flat (and level) bottom, diameter 3 cm., height 6 cm., stem 1 cm. in diameter and 3·5 cm. long, and capacity to the top of bulb about 8 ml., is gently evaporated to near dryness and then transferred to a hot plate at about 320° C. for 10–15 min. The flask is cooled, 0·1 ml. of nitric acid is again added, it is brought to near dryness and the flask is then transferred to the plate at 320° C. The ash may be white—indicating the complete destruction of the organic matter—at this stage but a third treatment is usual. To the dry ash is now added 2·5 ml. of 0·1 *N* nitric acid. The flask with contents is weighed, set on a hot plate to boil gently for about 10 min., reweighed, and the loss made up by addition of deionized water. From this test solution, 0·5-ml. portions are used for the determination of calcium with murexide as indicator, and 0·2-ml. portions for the determination of magnesium plus calcium with 'Eriochrome black *T*' as indicator.

Table 1. CALCIUM AND MAGNESIUM CONTENT OF NORMAL HUMAN BLOOD SERUM.
(mgm./100 ml. serum)

Reference	Method	No. of sera	Calcium: Mean	Calcium: Range	Magnesium: Mean	Magnesium: Range
1	Spectrographic	86	8·6	6·1–10·5	—	—
		103	—	—	1·90	1·21–2·54
2	Removal of calcium with oxalate and protein with trichloracetic acid. Colorimetry with 'Eriochrome black *T*'	24	—	—	2·10	1·75–2·50
3	Whole serum with murexide solution titrated with ethylenediamine tetra-acetic acid	710	9·7	8·9–10·5	—	—
3	Oxalate–permanganate	712	10·5	9·7–11·3	—	—
4	Flame spectrophotometric	22	10·8	—	—	—
4	Oxalate–permanganate	22	10·4	—	—	—
This work	Removal of protein by *p*H adjustment and heat (ref. 7) and colorimetry as described (ref. 6)	34	9·5	8·8–10·4	2·03	1·80–2·30

By this method calcium and magnesium added to serum have been precisely recovered, even in the presence of phosphate added up to 40 mgm./100 ml. serum.

The formation of complexes with the indicators by such trace metals in serum ash as copper, zinc, manganese and iron is considered to be negligible.

In Table 2 the analyses of the ash of thirteen sera from hospital patients, carried out as described above, are set alongside those obtained by the same analytical method from deproteinized serum filtrates prepared as previously described[7]. The close agreement of the two methods shows that suitably deproteinized serum filtrates yield true values for calcium and magnesium and renders the rather tedious ashing procedure unnecessary for routine purposes.

The oxalate–permanganate method commonly used in hospitals for the determination of calcium on 2-ml.

Table 2. CALCIUM AND MAGNESIUM DETERMINED ON SOLUTIONS OF THIRTEEN ASHED HOSPITAL SERA AND ON THEIR CORRESPONDING DEPROTEINIZED FILTRATES
(mgm./100 ml. serum)

	Calcium: Ash	Calcium: Filtrate	Magnesium: Ash	Magnesium: Filtrate
Mean	9·02	9·05	1·98	1·99
Range	7·9–10·0	8·0–9·9	1·80–2·25	1·80–2·20

serum samples gives values, on the present evidence, about 10 per cent too high. Nine sera from hospital patients were examined by both methods with the following results: oxalate method, mean 10·3, range 9·9–10·9 mgm./100 ml.; murexide method, mean 9·2, range 8·8–9·6 mgm./100 ml.

I am indebted to Dr. A. Preston, Oxford Regional Transfusion Service, for the normal bloods reported in Table 1. This work is part of a programme in the development of methods for the study of the blood-cerebrospinal fluid barrier in association with Dr. H. V. Smith, May reader in medicine in the University of Oxford, and is made possible by a grant from the Nuffield Foundation.

Tolerance of Skin Homografts related to Fatal Disease in Separated Rat Parabionts

Homotransplantation of viable tissue in adult individuals is possible only between identical or monozygotic twins. Successful homografting between dizygotic calves is due to anastomoses of placental vessels[1]. However, tolerance to homografts may be artificially induced[2] if animals are exposed to foreign tissue antigens during fœtal life. The upper limit of the period of tolerant response varies in different species but never extends far beyond birth[3]. In rats[4] tolerance may be induced as late as the second week of life.

In all these cases some form of parabiosis had existed and played the essential part in conferring tolerance. In an attempt to extend still further the 'adaptive' period it seemed justified to use parabiosis as a procedure of choice and see whether tolerance could be conferred at a more advanced stage of development, perhaps even in adult animals.

122 albino rats of both sexes, weighing 80–180 gm. (age, 5–13 weeks) and belonging to two unrelated random-bred strains, Y and W, were used; donor and recipient always belonged to a different strain and were of the same weight and sex. 38 animals were tested for compatibility with free full-thickness skin grafts; no graft survived beyond the twelfth day (mean survival time $W \rightarrow Y$, $8\cdot1 \pm 0\cdot4$ days; $Y \rightarrow W$, $10\cdot2 \pm 0\cdot4$ days; $0\cdot001 < P < 0\cdot01$). 84 animals were put in parabiotic union[5], making a total of 42 pairs; a tubed pedicle was formed from the dorsal lip of the skin wound in the donor and its distal free end sutured into a defect on the back of the recipient. Ether anæsthesia combined with urethane (100 mgm. per 100 gm. body-weight) was used throughout. The animals were separated on the fifth post-operative day; the tubed pedicle was ligatured and cut as near the graft as possible.

Results are presented in Table 1. Twenty-five separated hosts (59·5 per cent) completely destroyed their grafts by the tenth post-operative day. Eleven recipients (26·2 per cent) carrying viable grafts appeared at first to be healthy; suddenly, between the eighth and the twenty-fifth post-operative day, the animals became ill and died from within a few hours to a couple of days from the onset of the disease. The illness sometimes followed a more protracted course, the animal dying as late as the forty-third post-operative day. At time of death, the majority of grafts were fully preserved, showing good growth of hair. In some cases there was an initial necrosis of superficial epidermal layers, but that was as far as the immune reaction of the host could go except in two cases where grafts were considerably reduced in size. Regeneration took place only from graft. The best preserved part of the graft was always that farthest from the remnant of the tubéd pedicle.

Table 1. Fate of Grafts, Number of Recipients (with percentages in brackets)

Graft destroyed by the tenth day	Graft viable at time of host's death	Prolonged survival of graft	Alive with viable graft	Total
25 (59·5)	11 (26·2)	5 (11·9)	1 (2·4)	42 (100)

These 11 hosts are shown in Table 2. The cause of death was severe anæmia, pulmonary œdema and sometimes inanition. Post-mortem examination revealed atrophy of lymph glands with almost complete disappearance of thymus. The spleen and adrenals were usually enlarged. *Bartonella* parasites were not found. The incidence of disease was evenly distributed between the two strains and sexes. Five more hosts (11·9 per cent) recovered and destroyed their grafts between the fifteenth and the twentieth post-operative day. One host (2·4 per cent), a female weighing 170 gm., also recovered and is still in a good condition 72 days after the operation, carrying a partly preserved graft. This animal was challenged with a graft from the third strain on the eighteenth post-operative day. This it destroyed completely 13 days later. This very limited trial shows that a graft could be made tolerant of its host too, and that tolerance in these cases might be strain-specific.

The disease described herein strikingly resembles and is probably identical with the so-called 'parabiotic disease'[5]. The same might be true of conditions recently described in mice[6] and chicks[7]. Parabiotic disease is a very common occurrence in permanent parabiosis between genetically unrelated partners, and in our experience appears in one of the parabionts between the seventh and thirteenth post-operative days. The animal usually dies in a few days but may recover if separated from its partner sufficiently early (unpublished work). The graft and its host could be considered as two distinct animals and, though

Table 2. Incidence of Disease as related to Sex, Weight and Strain Combination; Onset of Disease and Survival Times of Tolerant Hosts*

Sex	Initial weight (gm.)	Strain combination	Onset of disease (days after operation)	Died (days after operation)	Condition of graft at time of death†
♂	80	$W \rightarrow Y$	11	13	f.p.
♂	80	$Y \rightarrow W$	12	13	p.p.

† f.p., fully preserved graft; w.p., well preserved graft; p.p., partly preserved graft.

tolerated, the graft always remains an intruder. It is not surprising, therefore, that the graft and its host could behave as true parabionts. During parabiotic union, the graft connected with donor via pedicle could be conditioned to produce a much greater quantity of antibodies against its host than a free graft could. However, the graft may not be the only source of antibodies. Adult blood cells can survive and perhaps even multiply in embryos and newly born animals[6,7]. It is not impossible that some of the adult cells, exchanged in enormous numbers as soon as cross-circulation is established on the fourth day of parabiotic union, may also survive and form antibodies against their host.

Effect of Oxy-chlororaphin on the Growth *in vitro* of *Streptomyces* Species and Some Pathogenic Fungi

During the course of other investigations, oxy-chlororaphin was found to inhibit strongly the growth of *Streptomyces* sp. 441. Chlororaphin (melting point 225° C. in nitrogen) was separated directly by centrifuging a five-day-old submerged culture of *Pseudomonas aeruginosa* containing glycerol (Sierra, G., and Veringa, H. A., unpublished work). Yields as great as 0·53 gm./l. were obtained (considerably greater than the yield of 5–16 mgm./l. obtained from a 14-day-old glucose culture at 28° C. by Birkofer[1]). Crystalline oxy-chlororaphin was obtained by dissolving chlororaphin in acetone (discarding the insoluble fraction). After cooling in contact with the air, the solution yielded crystals of oxy-chlororaphin. Several recrystallizations in acetone were necessary to obtain the pure compound (melting point 242° C.).

The activity tests were made by the usual method. Oxy-chlororaphin was incorporated into suitable agar media in an appropriate range of graded concentrations. The medium used was Sabouraud's glucose-agar, consisting of 0·5 per cent glucose, 2 per cent agar and 1·5 per cent 'Bacto-peptone' (Difco), the *p*H being adjusted to 5·6–5·8. *Streptomyces* cultures were incubated at 25° C. and cultures of pathogenic fungi at 37° C.

Manometric experiments show that a concentration of oxi-chlororaphin (333 parts per million) much higher than that necessary to inhibit completely the growth of *Candida albicans* in Sabouraud's glucose-agar medium does not affect the rate of uptake of oxygen from Sabouraud glucose by washed suspensions of this fungus. Oxy-chlororaphin (333 parts per million) does not affect the auto-respiration of *Candida albicans* in phosphate buffer (*p*H 6·4).

Table 1. EFFECT OF THE OXY-CHLORORAPHIN ON THE GROWTH OF SOME PATHOGENIC FUNGI AND *Actinomycetes*
The fungi were obtained from the Centraalbureau voor Schimmelcultures, Baarn, Holland; the *Actinomycetes* were from local stock

Cultures tested	Concentration of oxy-chlororaphin giving inhibition (parts/million)	
	Complete	Partial
Trichophyton mentagrophytes	12·5	6·3
Epidermophyton floccosum	25·0	12·5
Candida albicans	50·0	12·5
Microsporum audouini	25·0	12·5
Blastomyces dermatitidis	25·0	12·5
Streptomyces 404	25·0	6·3
Streptomyces 411	12·5	6·3
Estreptomyces 421	25·0	6·3
Streptomyces A. 425	25·0	6·3

No ill effects were observed in mice (weighing 20 gm.) injected intraperitoneally with 10 mgm. oxy-chlororaphin suspended in olive oil.

The action of oxy-chlororaphin certainly cannot be that of an antiseptic, in that it does not act as a general protoplasmic poison interfering with the respiration. As its action is more fungistatic than fungicidal, we may assume that it has some antagonistic action by which growth is prevented. Studies are under way to elucidate further the action of this compound *in vivo*.

A Strain of *Acetobacter aceti* giving a Positive Cellulose Reaction

A strain of *Acetobacter aceti* was isolated with many other acetic acid bacteria from ciders. It was identified by the use of Frateur's tests[1], and showed a positive cellulose reaction in addition to the usual characteristics of *A. aceti*, namely, catalase production, growth in Hoyer's medium, production of dihydroxyacetone from glycerol and gluconic acid from glucose. After staining the growth with iodine, and applying sulphuric acid, a blue colour developed. This reaction occurred slowly, and within 1–2 hr. the preparation appeared green. Microscopic examination revealed the presence of a non-cellular material which was blue in colour, intermingled with bacterial cells stained yellow by the iodine. The colour gradually intensified during the ensuing 24 hr. until the whole preparation then appeared blue.

The appearance of this organism in culture was quite unlike that of a typical cellulose producer, such as *A. xylinum*. It did not produce a cartilaginous pellicle in liquid media nor was the growth coherent on solid media, although it could be pulled into a short slimy string when touched with an inoculating needle. Further, the strain of *A. aceti* was actively motile and has been shown to possess peritrichous flagella (J. L. Shimwell, private communication).

There is thus a considerable difference between the cultural characteristics of this particular strain of *A. aceti* and of a typical cellulose producing *Acetobacter* species. In fact, the only characteristic which suggests the presence of cellulose in this culture of

A. aceti is the blue colour given with iodine and sulphuric acid. This suggests that the iodine–sulphuric acid test may not be specific for cellulose, which is not surprising since this appears to be a traditional and empirical test the mechanism of which is not fully understood. Alternatively, it may be that the amount of cellulose produced by this particular strain of *A. aceti* is insufficient to yield a tough leathery growth. The possibility that this organism may not produce true cellulose does not, however, affect its unusual taxonomic position: the only chemical criterion used by Frateur for cellulose production is the ability of a culture to produce a blue colour in the presence of iodine and strong sulphuric acid. This would include all true cellulosic organisms and any which produce substances giving a similar colour reaction.

As Shimwell[2] has already shown, the *Acetobacter* proper (excluding Frateur's *Suboxydans* group) are particularly prone to mutation or variation, one species easily changing to another by the loss or gain of certain biochemical activities. Shimwell[3] has suggested, on the basis of these findings, that it should be possible to find organisms with combinations of characteristics additional to the species listed by Frateur[1]. This has already happened since both Dr. Shimwell[3] and I (unpublished work) have found such organisms in vinegar brewing materials and ciders respectively. The significance of this strain of *A. aceti* is that it represents one end of the mutational range with *A. paradoxum* at the other, the former having all Frateur's characteristics positive and the latter all negative. It would, therefore, only appear to be a matter of time before all the 32 'species' postulated by Shimwell[3] are discovered.

Utilization of Thiocyanate by *Thiobacillus thioparus* and *T. thiocyanoxidans*

Two years ago we began to study whether *Thiobacillus thioparus* and *T. denitrificans* could break down thiocyanate oxidatively in the same way as *T. thiocyanoxidans*; it was immediately apparent that the former did, but since initial results suggested that the first and last of these organisms might nevertheless be separate species we decided not to publish our results at that time. All strains of *T. denitrificans* received were contaminated and since it has been our practice to work from single-cell culture we abandoned temporarily the study of *T. denitrificans*.

De Kruyff, van der Walt and Schwartz[1] have shown the capacity not only of *T. thioparus* but also of *T. denitrificans* to break down thiocyanates both aerobically and anaerobically in the presence of nitrate. They suggest that *T. thioparus* and *T. thiocyanoxidans* are one and the same organism; and with the present cultures this seems probable. The *T. thiocyanoxidans* which they studied is identical with the one we are now using, but it is not our original strain and there have been metabolic differences in the strains we have isolated from time to time. We have always accepted the view of Baalsrud[2] that the different *Thiobacilli* may perhaps represent a similar group of organisms rather than distinct species.

In the present work *T. thioparus* and *T. thiocyanoxidans* were compared for their ability to utilize both thiocyanate and thiosulphate for growth. They are grown at 30° C. on thiosulphate or thiocyanate media prepared as follows. Thiosulphate medium: 1·0 gm. sodium thiosulphate ($Na_2S_2O_3$ $5H_2O$), 0·35 gm. potassium dihydrogen phosphate, 0·14 gm. potassium hydroxide, 0·01 gm. ammonium chloride, distilled water to 100 ml. Thiocyanate medium: 0·025 gm. potassium thiocyanate, 0·35 gm. potassium dihydrogen phosphate, 0·14 gm. potassium hydroxide, 0·01 gm. ammonium chloride, distilled water to 100 ml.

After sterilizing at 15 lb./in.^{2} for 15 min. and cooling, 1·0 ml. of each of two cool, sterile salt solutions *B* and *C* were added: (*B*), 1·0 gm. magnesium sulphate ($MgSO_4.7H_2O$), 0·2 gm. anhydrous ferric chloride, 0·2 gm. manganese sulphate ($MnSO_4.4H_2O$), 3 ml. concentrated hydrochloric acid, distilled water to 100 ml. (*C*), 1 per cent calcium chloride solution. Viable cell counts were made by direct plating on thiosulphate media set with agar and by the technique of serial dilution which was slightly modified from that used in "Bacteriological Examination of Water Supplies"[3]. Thus an estimate could be made of the most probable number of cells present in a culture of each medium. To do this, five series of tenfold dilutions (10^{-3}–10^{-9}) of cultures of each organism in both types of medium were used. In preliminary experiments the values for cell population obtained from the tables of most probable number derived from the paper on "Bacteriological Examination of Water" were compared with those obtained from direct plate counts. Values so obtained were identical within the limits of error for the method employed. Results showed the infectivity of both organisms for thiocyanate and thiosulphate to be equivalent.

Organism	Substrate	Most probable number of cells/ml.
T. thioparus	Thiosulphate	$5 \cdot 3 \times 10^6$
T. thioparus	Thiocyanate	$2 \cdot 0 \times 10^6$
T. thiocyanoxidans	Thiosulphate	$5 \cdot 2 \times 10^6$
T. thiocyanoxidans	Thiocyanate	$8 \cdot 3 \times 10^6$

These results obviously suggested that *T. thioparus* had a similar or identical capacity with *T. thiocyanoxidans* for growing on thiocyanate.

As a further check on this similarity or identity of metabolic properties, several cultures of both organisms which utilized thiocyanate were back-inoculated in serial dilution into thiocyanate medium. The dilutions were 1/30, 1/900, 1/27,000, 1/810,000, etc. In two series *T. thioparus* in 1/30 dilution of the culture grew and utilized thiocyanate in these further cultures upon thiocyanate while another failed completely; whereas cultures of *T. thiocyanoxidans* could be diluted to 1/27,000 or 1/810,000 and continue to raise fresh populations of cells utilizing thiocyanate. These results disturbed the provisional conclusion that both organisms were in fact identical, but further studies were made using a modified technique. Serial dilutions were made into 5 ml. of medium (instead of 3 ml.) and incubated for 10 days, and since both organisms grow in thiosulphate these cultures were back-inoculated into both thiosulphate and

SUNVIC Recorder for gas chromatography

A trace with clearly defined peaks and smooth curves which facilitate accurate integration is characteristic of the Sunvic potentiometric recorder. This high-speed, self-balancing instrument can now be offered with several features which make it particularly suitable for monitoring the output from gas or vapour-phase chromatographs. These include:

Wide choice of chart speeds: 3″, 6″, 9″, 15″, 30″, or 45″ per hour, speed being easily selected during operation by a lever and gate mechanism.

Easy range changing: plug-in bobbins for 0-1mV, 0-5mV or 0-10mV.

High sensitivity: resolution of 0.1% of F.S.D.; accuracy of 0.5% of F.S.D.

Excellent speed of response: one second for full scale deflection.

Manual standardisation.

Right-hand zero position: 10″ scale, charts graduated 100-0.

Full specification in Data Sheet No. 4.
A copy will gladly be sent on request.

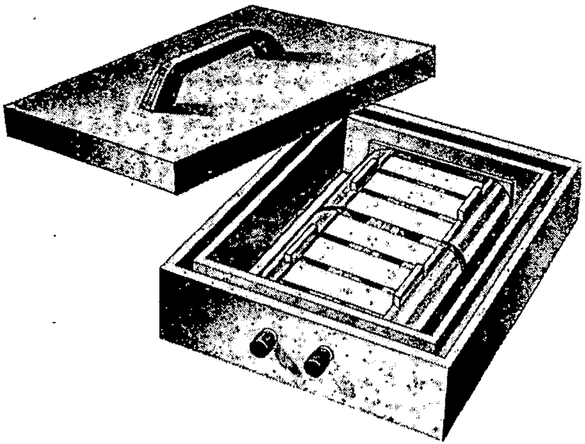
Shandon Universal Electrophoresis Apparatus

after Kohn



This vapour-tight tank is equally suitable for membrane filter, filter paper and starch electrophoresis.

The advantages of the new cellulose acetate membrane filter strips in electrophoresis include :

1. Sharp separation—in particular the albumin from the alpha fractions which may be difficult to separate on paper.
2. Adsorption is minimal and there is practically no tailing of fractions.
3. The membrane can be rendered completely transparent to both visible and U.V. light.
4. Some fractions may be demonstrated which are not seen on filter paper strips.
5. Small volume of sample required.
6. Short time to achieve separation (only 2 to 2½ hours for 12 cm. strip).

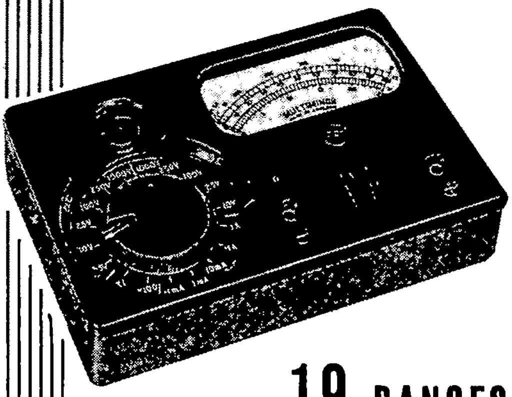
The MULTIMINOR

A new pocket-size instrument for the Laboratory worker



19 RANGES

THIS splendid new AVO Instrument has been developed to meet a definite demand for a sturdy pocket-size multi-range test meter at a modest price, suitable for use on modern electronic apparatus as well as for radio and television receivers, motor vehicles, and all kinds of domestic appliances and workshop equipment.

Readings are obtainable quickly and easily on a very open scale, and range selection is by means of a robust clearly marked rotary switch of the characteristic AvoMeter type. Measurements of A.C. and D.C. Voltage, D.C. Current, and Resistance are made by means of only two connection sockets.

Write for free illustrated leaflet

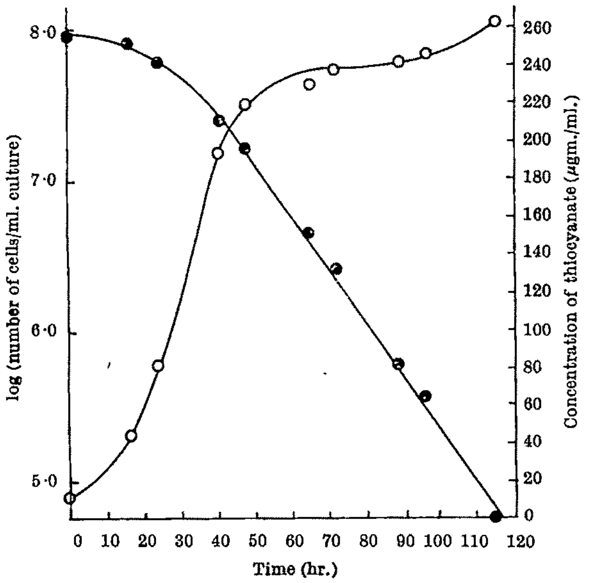

Fig. 1. Comparison of the growth of *Thiobacillus thiocyanoxidans* and its utilization of thiocyanate: ●, thiocyanate concentration (μgm./ml.); ○, log (number of cells per ml. of culture)

thiocyanate. The results were completely identical; growth occurred in thiosulphate medium throughout the whole range of dilution (1/30–1/24,300,000) and on thiocyanate medium down to a dilution of 1/810,000. Thus the identity of the present strain of *T. thiocyanoxidans* with *T. thioparus* as far as utilization of thiocyanate is concerned cannot be doubted—a result in conformity with the fuller findings of De Kruyff *et al.*

Fig. 1 represents the growth of viable cells of *T. thiocyanoxidans* with time, when the organism is grown at 30° C. in thiocyanate medium; the concurrent rate of disappearance of thiocyanate is also recorded. The viable cell population does not increase much after 48 hr. when approximately 20 per cent of the substrate has disappeared.

It should be mentioned, however, that cell autolysis seems to be rapid with this organism and there is abundant liberation of amino-acids and growth factors into the medium (including, Dr. E. Holdsworth tells us, some vitamin B_{12}) and thus many heterotrophs can grow in the supernatants which remain after the culture has apparently become sterile. We mention this fact since we do not accept the view of some distinguished workers that mass cultures of *T. thioparus* and *T. denitrificans* can be grown without careful sterilization and the resulting cells used for manometric and other studies, at least if the metabolism of these organisms are as close in metabolic properties to *T. thiocyanoxidans* as they appear to be.

Manometric experiments on the oxidation of various organic substrates by *T. thiocyanoxidans* have been carried out. Cells grown on thiosulphate medium show very little oxidation of formate or succinate, whereas cells grown on thiocyanate medium show a marked increase in the ability to oxidize both these substrates, especially in the case of formate. It has been observed that in cases where the cell suspension has a very high endogenous respiration, other substrates such as pyruvate have been oxidized. We have obtained colorimetric evidence which suggests that small amounts of formate may appear in cultures of *T. thiocyanoxidans* when growing upon thiocyanate.

We are grateful to De Kruyff *et al.* for directing our attention to the classical work of Beijerinck[4].

The Pennatularian Genus *Umbellula*

The examination of a numerically large collection of two species of *Umbellula* from the Swedish Deep-Sea Expedition[1] implied that many of the specific criteria hitherto employed would have to be dropped. Later investigation of an interesting series of antarctic and subantarctic specimens from the *Discovery* collections, together with a revision of the collections of *Umbellula* kept in the British Museum, has confirmed this assumption.

The species of *Umbellula* vary rather extensively in external aspect according to age and development and evidently also under different ecological conditions and more or less fortuitous contractions. In the first case, however, there are two characters which by their combinations, so to say, divide the genus into four groups. Hickson[2], in accord with Kükenthal[3], emphasized the importance of the presence or absence of spicules as *fundamentum divisionis*; but in his last paper Hickson[4] discarded Kükenthal's other fundamental character, namely, a square or a round axis. Both authors seem to have overlooked the connexions between degree of calcification, finer structure of the inner parts and its relation to the anatomy of the cœnosarcal layers, and the external aspect of the axis.

The structure of the spicules, too, is so characteristic that we can base two separate species on them alone: *U. durissima* has rod-shaped or feebly fusiform spicules, some of them with feebly knobbed ends; *E. thomsonii* has rod- or needle-shaped, three-flanged or -ridged spicules. The difference between the two species is further emphasized by the axis, which in *durissima* is round and almost devoid of carbonate of lime, while in *thomsonii*, on the other hand, it is quadrangular and strongly calcified.

The other and larger group of the genus is devoid of spicules. Here the axis is round in two species and all but completely devoid of carbonate of lime and extremely flexible. But the polyp clusters are distinctly different. *U. huxleyi* has rather small autozooids concentrated in a packed pompom at the end of the rachis, whereas *U. spicata* has its autozooids irregularly spread over an exceptionally long, distal, swollen part of the rachis as a long tassel.

The last two (or possibly three) species of the genus again have quadrangular axes but these are heavily encrusted with carbonate of lime. *U. pellucida* has small autozooids packed in a pompon terminally on the rachis; the entire specimens evidently do not exceed 35 cm. in total length, and their axes are very thin and brittle as compared with all the other species. *U. lindahli* is much more robust, and in most examples its axis is remarkably flexible, despite its rather strong calcification. Fully grown specimens of this species are seldom less than 40 cm. long and have large autozooids, which, especially in colder waters, are placed in great numbers in more open tassels.

The six species mentioned are the only ones which are sufficiently described at present. Although the distribution of *U. encrinus* indicates that it is an arctic species, its structure suggests that it is only an extreme, ecological form of the cosmopolitan *U. lindahli*; this question needs further examination. A full report on the collection will appear in the "Discovery" Reports.

Effect of Metal Ions on the Development of Wheat Stem Rust

DURING a study of the effect of benzimidazole, dimethylbenzimidazole, glucose and metal ions on the development of rust in detached leaves, certain metal ions have been noted to be extremely effective in the prevention of rust development in detached wheat leaves of both resistant and susceptible varieties.

Wheat seedlings at the two-leaf stage were inoculated with urediospores of *Puccinia graminis tritici* and incubated for 24 hr. in a moist chamber. At the end of incubation, the leaves were excised and floated on various solutions of metal ions in Petri plates. The development of rust was noted on the ninth day after excision of the leaves. Results of the effect of various metal ions on rust development in detached Khapli leaves are given in Table 1. Khapli leaves, normally resistant to race 15*B*–1, became susceptible after detachment when floated on water. From the results, it is evident that the rust development in these leaves is markedly checked by nickel ions even with a concentration as low as 0·5 p.p.m. Cobalt, molybdenum, copper, manganese and iron have no effect on rust development. Cobalt induces chlorosis in the leaves with concentrations of 2–4 p.p.m., and any concentration greater than this has been found to be toxic to the excised leaves. Zinc also produces chlorosis, but to a lesser extent, and it is not toxic at higher concentrations (10 p.p.m.). Zinc shows no effect on rust development at the lower concentrations and only slightly at higher ones, but results with zinc varied considerably. On the other hand, nickel yielded consistent results and did not induce chlorosis in the leaves with any of the concentrations tested.

Table 2. EFFECT OF NICKEL AND COBALT IONS ON THE DEVELOPMENT OF *Puccinia graminis tritici*, RACE 15*B*-1, ON DETACHED LEAVES OF LITTLE CLUB AND MARQUIS. OBSERVATIONS WERE MADE ON THE NINTH DAY AFTER EXCISION OF LEAVES

Variety	Rust development						
	Cobalt (p.p.m.)			Nickel (p.p.m.)			
	0	2	4	0	2	3	4
Little Club	++++	++++	++++	++++	+*	+	nil
Marquis	++++	++++	++++	++++	nil	nil	nil

* +, The type of rust reaction of attached resistant Khapli leaves.

Studies on the effect of metal ions on the rust development in detached leaves of susceptible varieties (Little Club and Marquis) were made only with cobalt and nickel. Results are given in Table 2. Cobalt shows no inhibition of rust development; on the other hand, nickel is very effective in the prevention of rust development in the detached leaves of susceptible varieties. With these varieties, a slightly higher concentration of nickel is necessary in order to obtain the same degree of inhibition as that found on Khapli leaves.

The effect of these metals on the inhibition of rust development in detached leaves does not correspond to their effect on germination and growth of urediospores of *P. graminis tritici*. For example, in descending order of effectiveness at 4 p.p.m., nickel, iron, zinc and copper inhibit both the germination and growth, cobalt inhibits growth only, having no effect on germination, whereas manganese and molybdenum have no apparent effect on either phenomena.

Sempio[1] had also shown that infection of *Puccinia triticina* was greatly reduced by adding nickel (*M*/7500) to the nutrient solution. Because of the results reported here it would be unwise to state categorically that nickel acts as a fungicide *per se*. Its effects on the host may be equally important and we have found that it has the effect of slowing down both the synthesis and breakdown of chlorophyll in uninfected detached etiolated and green leaves.

Table 1. EFFECT OF VARIOUS METAL IONS ON THE DEVELOPMENT OF *Puccinia graminis tritici*, RACE 15*B*-1, IN DETACHED KHAPLI LEAVES OBSERVATIONS WERE MADE ON THE NINTH DAY AFTER EXCISION OF LEAVES

Metal ion	Rust development								
	Concentration of metal ions (p.p.m.)								
	0	0·1	0·25	0·5	1·0	2·0	3·0	4·0	5·0

Photoperiodic Induction of Flowering in Black-Currant

During the course of a detailed morphological investigation of flower-initiation in black-currant (*Ribes nigrum*) it was observed that under field conditions flower primordia are normally initiated in the axillary buds following the cessation of active extension growth of the shoot. This observation suggested that possibly flower initiation depends on the cessation of extension-growth and that treatments which bring about the latter might also induce flowering. It is known that this species grows actively under long-days but rapidly becomes dormant under short-days[1], and the following experiments were therefore carried out to test whether short-day treatment promotes flower-initiation.

Plants of the variety Baldwin raised from hardwood cuttings were allowed to grow under natural long-day conditions until they had attained a height of about 50 cm. They were then selected for uniformity and divided into three groups which were exposed to the following photoperiodic conditions, respectively: (1) 8-hr. photoperiods (29 plants); (2) 18-hr. photoperiods (19 plants); and (3) natural day-length conditions (10 plants). The treatments were commenced on June 21 and within 2–3 weeks the plants under short-day conditions were observed to have ceased extension growth. On July 29 (after 5 weeks treatment), 14 of these short-day plants were transferred back to long-days, under which conditions the axillary buds expanded in 2–3 weeks, and a high proportion of the axillaries in the upper part of the shoots produced flowers which set fruit in September. The plants maintained under long-day throughout continued active extension-growth until the experiment was terminated on September 12. At this date many of the axillary buds had elongated into short shoots which were entirely vegetative. The plants maintained under natural day-length conditions ceased extension-growth at the beginning of August and were afterwards found to have initiated flowers in the normal way.

Further experiments with plants decapitated before treatment (as part of another investigation) have confirmed these results and have indicated that a period of exposure to 16 short-days is sufficient to induce flowering, provided that fully expanded leaves are present on the plants. This latter result is directly comparable with the conditions necessary for photoperiodic induction of flowering in herbaceous plants and suggests that short-day treatment may have a direct effect on flower-initiation in black-currant, independently of any effect on extension-growth. This possibility is being further investigated.

Effect of Number of Sprouts per Set on Yield and Grading of Main-Crop Potatoes

It is well known that the number of stems formed by a potato plant profoundly affects the size and number of tubers produced[1,2], and that some varieties tend to produce many stems and thus a high proportion of small unsaleable tubers[3]. If sprouted seed of such varieties with only one or two sprouts per set are planted, the resulting crop contains a high proportion of ware (table potatoes)[4].

In 1957 the effect of sprouted seed tubers on stem and tuber production was investigated in respect of four maincrop varieties (King Edward, Majestic, M.A.N.I. Seedling 480/51 and Ulster Supreme) in two seed sizes (mean weights 44 gm. (1½ oz.) and 80 gm. (2⅚ oz.)). Three sprout treatments were used: (*a*) all but one sprout removed; (*b*) all but three sprouts removed; (*c*) multiple sprouts as grown. Spacing was standardized at 36 in. apart each way. The plants were lifted by hand and recorded individually (Tables 1 and 2).

Table 1. MEAN NUMBER OF MAIN STEMS AND TUBERS PER PLANT

Variety	Seed size	Mean No. of main stems per plant			Mean No. of tubers per plant		
		a	*b*	*c*	*a*	*b*	*c*
Majestic	*M*	1·0	2·2	2·5	11·0	14·5	17·3
Ulster Supreme	*M*	1·0	2·7	3·7	11·0	17·0	19·4
King Edward	*S*	1·0	2·7	2·9	12·3	19·0	23·4
King Edward	*L*	1·0	3·0	4·6	19·8	23·7	32·2
King Edward	*M*	1·0	2·8	3·7	16·1	21·3	27·8
M.A.N.I. 480/51	*M*	1·0	2·7	9·5	20·5	22·9	45·7

S, Small seed; *L*, large seed; *M*, mean of small and large seed.

Table 2. MEAN NUMBER OF TUBERS PER PLANT IN EACH GRADE IN TREATMENTS *a* and *c*, SEED SIZE AVERAGED

Variety	Treatment	Grade			
		1	2	3	4
Majestic	*a*	2·9	3·5	2·1	2·5
Majestic	*c*	1·5	5·5	5·3	5 0
Ulster Supreme	*a*	5·5	3·2	1·0	1·3
Ulster Supreme	*c*	2·9	7·7	5·7	3·1
King Edward	*a*	1·7	4·8	5·2	4·4
King Edward	*c*	0·7	3·5	10·4	13·2
M.A.N.I. 480/51	*a*	2·1	6·1	5·9	6·4
M.A.N.I. 480/51	*c*	0·3	4·4	11·5	29·5

Grades 1, 342 gm. (12 oz.) and greater outsize; 2, 172–341 gm. (6–12 oz.), large ware; 3, 71–171 gm. (2½–6 oz.), small ware; 4, 2–70 gm., seed and chats.

There was a wide variation in behaviour between varieties in the number of stems and tubers formed[5], and their grading. At one extreme, M.A.N.I. 480/51 formed too many stems and tubers on treatment *c* (multiple sprouts) for satisfactory ware production, yielding a mean of 9·5 stems and 45·7 tubers per plant. Up to 17 stems and 69 tubers were recorded on a single plant, such plants producing little marketable ware. On treatment *a* (single sprouts) these were reduced to 1·0 and 20·5 respectively, when this variety appeared to be a useful cropper of large red ware.

At the other extreme Majestic produced fewer stems (mean 2·5) and tubers (mean 17·3) with a low proportion of small tubers in treatment *c*. This variety rarely formed four or more stems per plant, which produced an increased number of smaller tubers. In treatment *a* the number of tubers was reduced, but there was an excessive proportion of large coarse tubers unfit for sale. The behaviour of Ulster Supreme was comparable to Majestic, and in both these varieties reducing the sprouts to one per set was unsatisfactory.

King Edward was intermediate between these extremes, but the amount of large ware was greatly increased by reducing the sprouts. Treatment *a* reduced the total number of tubers and increased the proportion of large ware. The behaviour of the two seed sizes in this treatment should be noted. Treatments *b* (large seed) and *c* (small seed) were practically identical, producing a mean of approximately three stems per set and similar numbers of tubers. Treatment *c* (large seed) tended to produce more stems and a greater number of tubers, ranging up to six stems and 43 tubers on a single plant. This treatment was unsatisfactory for ware production.

The number of stems formed per plant appeared generally to correspond to the number of sprouts per set planted, but with marked varietal differences. Considerable suppression of sprouting was noted. Varieties (King Edward and M.A.N.I. 480/51) which often produce a high proportion of small tubers benefited markedly from sprout reduction, whereas the others did not. Large seed tended to form more sprouts and stems than small seed[6,7] and a higher proportion of small tubers. Full details are reserved until it is possible to include the 1958 results, when a complete account of the work will be published.

Grateful acknowledgment is made to Mr. C. V. Dadd of the National Agricultural Advisory Service, Cambridge, for his help, to the Governors of this Institute for provision of facilities, and to the Ministry of Agriculture, Northern Ireland, for co-operation and for supplying part of the seed.

Chromosome Breakage at High Radiation Dose-Rates

THE variation of the frequency of chromosomal aberrations as a function of radiation dose-rate has been the subject of numerous experimental investigations, and the results of such studies have been of considerable importance in formulating theories of the basic mechanisms of radiation action[1]. With the recent availability of radiation sources of great intensity, such as electron linear accelerators, and the development of reliable dosimetric techniques for use at these intensities, the extension of studies on chromosomal breakage into the range of the extremely high dose-rates has become feasible.

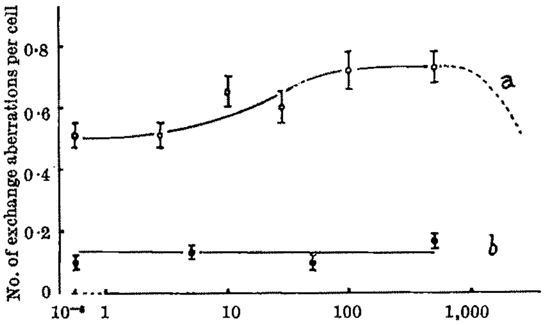

Fig. 1. Variation of the frequency of exchange aberrations with dose-rate for a constant dose of about 400 rads. *a*, In air; *b*, in nitrogen

An exploratory investigation of chromosomal breakage in microspores and pollen has been carried out at dose-rates up to 4×10^6 rads/sec. using the electron and X-ray beams from the 15-MeV. linear accelerator at St. Bartholomew's Hospital. Special ionization chambers in conjunction with 'Perspex' dosimeters[2] were used in the determination of the dose applied. The biological material has been *Tradescantia paludosa* (clone 3 of Sax), made available to us through the courtesy of Mr. George Lacour and the John Innes Horticultural Institution. Chromosome aberrations in *Tradescantia* microspores examined 4–5 days after irradiation have been studied in most of the work to date.

All results so far obtained indicate a definite and significant decrease in the frequency of aberrations at dose-rates of more than 10 rads/sec., for material irradiated in air. This decrease in the frequency of aberrations has been observed repeatedly for deletions as well as for exchange aberrations. Typical results obtained from one set of experiments are shown in Fig. 1, which relates to irradiations carried out in air and in nitrogen with 14-MeV. electrons. The dose was about 400 rads for both media. The dotted portion of the upper curve shows the expected frequencies of exchange aberrations at lower dose-rates reported by Wolff and Luippold[3]. The curve for irradiations in air shows that the frequency of exchange aberrations has a constant value over a range of medium dose-rates and falls off at both high and low dose-rates. In nitrogen neither the deletions nor the frequency of exchange aberrations decreases at high dose-rates.

At present there is no satisfactory explanation of the drop (40–50 per cent) observed at high dose-rates from the plateaux at medium dose-rates, although mechanisms involving recombination of secondary organic free radicals appear qualitatively plausible. An alternative explanation of this result based on partial temporary anoxia resulting from immediate consumption of oxygen under intense bursts of radiation has also been proposed. A preliminary experiment carried out under increased oxygen tension suggests that the second explanation may be correct.

A complete account of this work will be published elsewhere.

We wish to acknowledge financial support from the British Empire Cancer Campaign and the Treasurer and Board of Governors of St. Bartholomew's Hospital. We also wish to thank Prof. J. Rotblat,

head of the Linear Accelerator Research Unit at St. Bartholomew's Hospital, for his help and co-operation.

Competition between Genotypes in *Drosophila melanogaster*

It has been shown by Birch[1] that the main competitive effect in *Drosophila pseudo-obscura* is between larvæ. Lewontin[2] studied the larval viabilities of various strains of *D. melanogaster* mixed with a white-eyed stock and found that the viability of a genotype is partially dependent on the genotypes co-existing with it.

In a two-point back-cross linkage experiment, the proportion of competing genotypes is different in each phase. Considering such an experiment for two factors *a* and *b* which are somewhat inviable in the recessive state, four genotypes are obtained in the offspring:

AB/ab, Ab/ab, aB/ab, ab/ab

In coupling, the most and least viable genotypes, *AB/ab* and *ab/ab*, predominate in the progeny, and hence under crowded conditions there will be a tendency for elimination of *ab/ab* flies. In repulsion, *Ab/ab* and *aB/ab* predominate and the main competition is between these two genotypes. The recombinants *AB/ab* and *ab/ab* will not compete with each other to any great extent but will compete mainly with the parentals. Hence the elimination of *ab/ab* will not be as great as in coupling. Thus in very crowded conditions a difference in the viability relations can be expected between coupling and repulsion.

Using the two sex-linked genes, white (*w*) and miniature (*m*), results for coupling and repulsion (Table 1) were collected for two-point backcrosses in *D. melanogaster* for three levels of competition which can be termed low, medium and high levels. For all levels, flies were mated for 48 hr. For the low level one pair was mated in a ½-pint milk-bottle, for the medium level one pair in a small vial, and the high level six pairs in a small vial.

Assuming no competition between larvæ, the ratios *wm* : + + and *w*+ : +*m* should not vary between coupling and repulsion. A simple contingency χ_1^2 may be done within each level to test this (Table 2).

The only significant result is for the high level where the ratio *wm* : + + varies between coupling and repulsion. In coupling, the *wm* flies are of much poorer viability than the + + flies, but in repulsion this is not so. The less extreme contrast, *w*+ and +*m*, does not show any variation between coupling and repulsion.

Table 1. Results for *w–m*

		wm	*w*+	+*m*	+ +	Total
Low	*C*	478	236	211	483	1,408
	R	318	529	569	289	1,705
Medium	*C*	409	205	236	407	1,257
	R	190	407	424	200	1,221
High	*C*	506	288	300	659	1,753
	R	580	976	1,062	553	3,171

C, Coupling; *R*, repulsion.

Table 2. χ_1^2 Tests for *wm* : + + and *w*+ : +*m* within Each Level of Competition

Levels	*wm* : + +		*w*+ : +*m*	
	χ_1^2	*P*	χ_1^2	*P*
Low	0·71	$0·3 < P < 0·5$	2·53	$0·1 < P < 0·2$
Medium	0·16	$0·5 < P < 0·7$	0·62	$0·3 < P < 0·5$
High	13·56	$P < 0·001$	0·18	$0·5 < P < 0·7$

This difference arises as a result of differential competition between larvæ according to the proportions of competing genotypes present. The implication of the viability of a genotype varying according to the competing genotypes has not been stressed, although Haldane[3] deals with it in an early paper. In natural conditions, where competition is much more severe than in artificial laboratory conditions, such effects must assume some importance. Thus selective advantages and disadvantages of a gene or genotype must be considered in relation to the food available, and the types and proportions of the other genotypes in the population.

Further discussion with additional results will be published elsewhere.

Effects of Environment (Radiation, Substrate and Allelic Genes) on the Melezitose Gene in *Saccharomyces*

The melezitose locus (*MZ*) in *Saccharomyces* controls the formation of the adaptive enzyme, melezitase, which acts on five substrates: turanose (*T*), maltose (*M*), sucrose (*S*), methyl-α-D-glucopyranoside (*G*), and melezitose (*Z*), each of which may serve as an inducer of melezitase[1-3]. Seven different variations (alleles) of this gene are known and are designated *TMSGZ*, *TMSGz*, *TMSgZ*, *TMSgz*, *TMsgz*, *Tmsgz* and *tmsgz*[3]. The capital letters indicate the substrates which are capable of inducing melezitase in glucose-grown cultures. Cells in which melezitase has been induced by one of the substrates to which it responds adaptively are able to split the substrates which do not act as inducers in that specific genotype without further adaptation. For example, a glucose-grown culture carrying *TMSgz* responds to neither methyl-α-D-glucopyranoside nor melezitose, but splits both these substrates after exposure to turanose, maltose or sucrose.

The first evidence of the *MZ* series came from hybridization experiments. The various genes produced by hybridization were inferred to have resulted from gene conversion in the hybrid since they were stable in the vegetative condition and arose at meiosis of heterozygotes only.

Five genes of the *MZ* series were obtained by ultra-violet radiation of *TMSGZ*. The limited kinds which were produced by gene conversion and ultra-violet radiation indicate that alterations of the gene

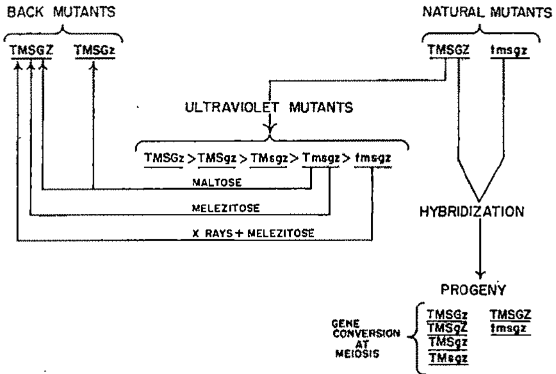

Fig. 1

occur in an orderly manner[3]. This view was further supported by the relative frequencies of the different types of mutants induced by ultra-violet radiation.

Back mutation of the gene occurred from 'recessive' to 'dominant' when the ultra-violet-induced mutants (*tmsgz* excluded) were exposed to substrate which they could not utilize. The gene *tmsgz* had proved refractory to back mutation by substrate alone (or by ultra-violet and substrate). Mutations of *tmsgz* back to *TMSGZ* were induced by the combined action of X-rays and substrate[4]. The linear mutation–dose-response curve for X-ray-melezitose induced back mutants, and the failure to detect intermediate variations of the gene indicates that the mutation from *tmsgz* to *TMSGZ* is a single event (Pittman, D., Lewis, C. H., and Lindegren, C. C., in preparation). The synergistic effect of X-rays and melezitose being necessary to induce the single event suggests that X-rays render the gene mutable and melezitose specifies the mutation. The five traits of the back mutant are transmitted as a single gene in hybrids. The cleavage-rate of melezitose by X-ray-induced back mutants was lower than that of a wild type strain, indicating that the 'new' gene was not so potent functionally as the 'original' gene.

Fig. 1 is a diagram of the various manifestations of the gene and the effect of various agents upon them. Ultra-violet radiation effects the degradation of *TMSGZ* to produce five different genes with the relative frequencies: *TMSGz* > *TMSgz* > *TMsgz* > *Tmsgz* > *tmsgz*. Each of the 'degraded' genes is characterized by the inability of the mutant to respond adaptively to one or more of the inducing substrates by the induction of the enzyme melezitase. The fact that only five of 31 possible genes are produced by ultra-violet radiation of *TMSGZ* supports the view that the degradation of the gene is an orderly process, and that the gene is limited in the number of its manifestations. The 'intermediate' genes respond to substrate alone (without the mediation of radiation) by back mutation. Back mutation of *Tmsgz* on melezitose produced only *TMSGZ* while back mutation of *Tmsgz* on maltose produced both *TMSGZ* and *TMSGZ*, indicating that substrate specifies the back mutation to a limited extent. The fact that back mutation from those induced by ultra-violet radiation can occur led to the inference that the phenotypes of the intermediate genes do not result from deletion but rather from alteration of the gene. The gene *tmsgz*, which is incapable of responding as an inducer to any of the substrates, is incapable of reverse mutation by exposure to substrate only. Although *tmsgz* cultures are refractory to back mutation when plated on the five substrates, if exposure to substrate is preceded by X-irradiation, back mutation occurs. It is inferred that X-rays and the substrate act synergistically and that X-rays render the gene mutable and substrate specifies the mutation which shall occur. In the absence of either X-rays or substrate, mutations occur at a very low rate. The X-ray-substrate back mutants are of two types—either the totipotent *TMSGZ* or $TM^vSG^vZ^v$, the latter being variable in their capacity to respond to the inducers maltose, methyl-α-D-glucopyranoside and melezitose. The variable mutants may be originally *TMSGZ* but may lose some recently acquired capacities rather readily. The stability of *S* may mean that a mutation at another locus (*SU*) had occurred. These variable mutants are under further investigation to determine the nature of the instability induced by radiation. The reconstituted *TMSGZ* gene is functionally less active than the original gene. These 'restorative' mutations resemble the repair of a damaged locus rather than the construction of a 'new' gene. A capacity not found in the genus might be introduced by exploitation of the combined effects of unequal crossing and the synergistic effects of substrate and radiation.

This work has been supported by grants from the U.S. Atomic Energy Commission, *AT* (11–1) 424, and the Damon Runyon Memorial Fund (*DRG* 407).

Abundance of Pogonophora

A previous communication[1] reported the occurrence of Pogonophora in the Atlantic. Since then another cruise has been made on R.V. *Sarsia*, and more preserved material examined. Species of *Siboglinum* have now been taken at six stations along the continental slope between lat. 47° 56′ N., long. 7° 56′ W. and lat. 48° 32′ N., long. 10° 11′ W. at depths ranging from 300 to 710 fathoms, and specimens of at least three of them brought back alive to the laboratory. Species of the same genus have also been found in bottom samples taken by Mr. N. A. Holme in 1956 at depths of only 80–90 fathoms off Dingle Bay on the west coast of Ireland.

Clearly, these interesting relatives of the chordates must be widely distributed in communities on muddy bottoms, and not only in deep water. It is surprising that they have escaped previous notice, as the areas where they have now been found were among the first to be dredged and trawled over by marine zoologists. No doubt the superficial resemblance of the tubes to the fibres used in dredge and trawl netting has hindered earlier recognition.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Zoologist (with a degree) in the Physics Department to assist in studies of effects of radiation on bone—The House Governor, Westminster Hospital, London, S.W.1 (July 29).

Assistant Lecturer in Soil Physics in the Department of Agricultural Sciences—The Secretary, School of Agriculture (University of Nottingham), Sutton Bonington, near Loughborough (July 31).

Assistant Lecturer in the Department of Pharmaceutics, and an Assistant Lecturer in the Department of Pharmaceutical Chemistry—Clerk to the Council, School of Pharmacy (University of London), P.O. Box 125, 29/39 Brunswick Square, London, W.C.1 (July 31).

Technical Officer (A.I.M.L.T. or with a science degree, competent in blood group serology, and preferably experience in plasma drying and/or fractionation) to act as Deputy to the Chief Technical Officer—The Medical Director, National Blood Transfusion Association, Pelican House, 52 Lower Leeson Street, Dublin (August 6).

Research Fellows in Chemistry, Metallurgy, Electrical Engineering and Physics—The Registrar, College of Technology, Gosta Green, Birmingham 4 (August 7).

Assistant Experimental Officer (female, with a degree in a biological subject and practical experience in bacteriological methods and techniques), for supervisory duties in media preparation and general laboratory management and to assist in experimental work on ecology of soil micro-organisms—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (August 9).

Assistant Lecturer or Lecturer in the Department of Inorganic and Physical Chemistry—The Registrar, The University, Liverpool (August 9).

Demonstrator in Botany—The Registrar, The University, Leeds 2 (August 9).

Lecturers or Assistant Lecturers (with an honours degree in mathematics and research experience in either pure mathematics or mathematical physics) in Mathematics—The Registrar, Manchester College of Science and Technology, Manchester 1 (August 14).

Animal Physiologist (graduate with qualifications and research experience in physiology) at Canterbury Agricultural College, University of New Zealand, to undertake research work with animals and some lecturing duties—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (August 15).

Assistant Lecturer (preferably with special interests in human geography) in Geography—The Assistant Registrar, The University, Edmund Street, Birmingham 3 (August 16).

Post-doctoral Fellow (Ph.D. standard with research experience in organic chemistry) in the Department of Organic Chemistry to undertake work on metabolics of marine micro-organisms—The Registrar, The University, Liverpool (August 16).

Research Officer (with an honours degree in science (majority in botany and plant physiology) or agricultural science, and postgraduate experience in relevant fields) in the Plant and Soils Research Laboratory, Division of Plant Industry, C.S.I.R.O., Brisbane, Australia, to conduct a research programme on the effects of the climatic factors of the environment on the growth and reproduction of subtropical and tropical pasture and crop plants, with particular attention to the effects of temperature and photoperiod—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting Appointment No. 146/108 (August 16).

Senior Lecturers or Lecturers (male, with an appropriate first- or second-class honours degree and preferably teaching experience) in Mathematics (preferably Applied Mathematics), Mechanical Engineering, Electrical Engineering, Radar and Telecommunications, and Engineering Physics at the Royal Military College of Science, Shrivenham, Berkshire—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A262/8A (August 18).

Lecturer in Philosophy at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, August 22).

Lecturer (with at least a Master's degree in chemical engineering and some experience in the teaching of chemical engineering instrumentation) in Chemical Engineering at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, August 22).

Geologist (with an honours degree in geology requiring a four-year course at a recognized university, and preferably previous experience) with the Southern Rhodesia Government—The Secretary (R), Rhodesia House, 429 Strand, London, W.C.2 (August 23).

Chemists, Scientific Officer or Senior Scientific Officer Grade (with a first- or second-class honours degree in chemistry or equivalent, and for Senior Scientific Officer posts, some research experience) at the Road Research Laboratory (D.S.I.R.), Harmondsworth, Middlesex, for research into the use and performance of bituminous road materials and on problems arising from the presence of organic matter in soils—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting F.475/8A (August 29).

Demonstrator in the Department of Botany—The Registrar, The University, Nottingham (August 29).

Curator (preferably aged 35–40, with an honours degree in zoology) of Mammals—The Secretary, Zoological Society of London, Regent's Park, London, N.W.1 (August 31).

Demonstrator in Physics—The Registrar, Trinity College, Dublin (August 31).

Lecturer (with an honours degree in chemistry and preferably experience in radiochemical techniques) in Chemistry at the University of Canterbury, Christchurch, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, August 31).

Assistant Lecturer in the Department of Geography—The Registrar, The University, Liverpool (September 6).

Lecturer in Microbiology at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, September 8).

Chair of Industrial Microbiology—The Secretary, University College, Dublin (October 1).

Professor of Mathematics at the University of Tasmania, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, October 13).

Assistants, Grade B (2) (with an honours degree in physics and an interest in some branch of applied physics) for Physics—The Clerk to the Governors, South-East Essex Technical College, Longbridge Road, Dagenham, Essex.

Laboratory Steward (preferably with some knowledge of chemistry and experience of handling scientific apparatus) for Chemistry and Biology Laboratories, Coventry Technical College—The Director of Education, New Council Offices, Earl Street, Coventry.

Lecturer in Mathematics to develop courses in methods of teaching mathematics for students training to teach in Technical Colleges—The Director, Training College, Queen Street South, Huddersfield.

Lecturer in Physics, able to teach up to B.Sc. General and Grad.Inst.P. standard—The Principal, Technical College, Brunswick Road, Gloucester.

Lecturer (with a good honours degree or equivalent, together with teaching, research, or industrial experience, and able to offer specialized knowledge of a branch of applied physics) in Physics—The Clerk to the Governors, Mid-Essex Technical College and School of Art, Market Road, Chelmsford, Essex.

Principal (with high academic qualifications and appropriate educational and administrative experience)—The Clerk to the Governing Body, Northern Polytechnic, Holloway, London, N.7.

Reader in Statistics—The Professor of Statistics, University of Melbourne, Carlton N.3, Victoria, Australia.

Research Assistant to assist in postgraduate laboratory teaching of telecommunication, and to assist research in speech and aural perception—Dr. E. C. Cherry, Electrical Engineering Department, Imperial College, London, S.W.7.

Research Assistants in the Department of Chemistry for experimental work on the thermodynamic properties of mixtures—The Registrar, The University, Reading.

Research Chemist (with a first- or second-class honours degree in chemistry and preferably research experience in physical chemistry or chemical engineering), to lead a small team engaged on studying the chemical aspects of new processes and providing chemical and physical information on which chemical plant designs are to be based—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting Ref. 1912/34.

Research Fellow or Assistant (with a good scientific background and a sound knowledge of aerodynamics and preferably experience of flight research) in the Department of Flight, to assist in an expanding programme of full-scale aerodynamic research—The Recorder, The College of Aeronautics, Cranfield, Bletchley, Bucks.

Senior Laboratory Technician, Class 1, in the Biochemistry Section of the Group Pathology Service—The Group Secretary, York (A) and Tadcaster Hospital Management Committee, Bootham Park, York.

New Books

BIBLIOGRAPHY OF FOOD

By E. ALAN BAKER, A.L.A.
Librarian, Ministry of Food, 1949–55
and D. J. FOSKETT, M.A., F.L.A.
Information Officer, Metal Box Co., Ltd., 1948–57

This bibliography sets out to demonstrate the wealth of material available to the food chemist and the food scientist. International in scope, it includes most of the significant works of authors on nutrition, food economics and food technology published in the English language, together with a representative selection of material from most foreign sources. Indeed, foreign literature coverage amounts to 30 per cent.

Only published material has been included. Material prepared privately by research and other organizations has not been listed, though the names and addresses of such organizations are included, giving added value to the work as a modern directory for the Industry. The book forms an essential reference tool for all engaged in work on nutrition, food and drink processing, food technology, distribution, packaging, economics, and the legal aspects of the food industry.

Price 63s.

HEAT EXCHANGERS

Applications to Gas Turbines

By W. HRYNISZAK, D.Sc., Dip.Ing.,
C. A. Parsons & Co., Ltd.

This book is not concerned with the process of heat transfer itself, but with the apparatus performing this transfer and the best way of designing and fitting it into a gas turbine so as to obtain, depending on its application, an economical unit. It is felt that the manner in which the thermodynamical optimization of the gas turbine air preheater has been treated will be of particular interest in connection with supercritical steam cycles and nuclear power applications.

The technical literature has been sadly lacking in an up-to-date treatment of the subject. The present treatise by Dr. Hryniszak, who enjoys an international reputation in the field of thermodynamics, will be welcomed by the engineer and will not be without interest to the physicist who is more and more becoming involved in direct applications of thermodynamics.

Price 63s.

The Kinetics of VINYL POLYMERIZATION by Radical Mechanisms

By C. H. BAMFORD, Ph.D., W. G. BARB, Ph.D., A. D. JENKINS, Ph.D., F.R.I.C., and P. F. ONYON, Ph.D., F.R.I.C.

This book presents a balanced account of the theoretical and experimental foundations on which our understanding of the kinetics and mechanism of these reactions is based. It will be of use not only to those chemists having a particular interest in mechanism of free radical reactions but also to those engaged in the industrial application of vinyl polymerization who wish to learn more of the fundamentals.

The first two chapters discuss the broad theoretical concepts on which the subject rests, restricting the treatment to a consideration of the average properties of radicals and polymer molecules. Chapter Seven, which deals with the statistical aspects of vinyl polymerization, supplies the fine structure necessary for a more detailed understanding of the systems. The remaining chapters summarize the experimental results for the most important monomers and discuss further developments of the general theory.

LECTURES AND COURSES

HUDDERSFIELD COLLEGE OF TECHNOLOGY

REGIONAL COLLEGE

Principal: Dr. W. E. Scott, M.B.E.

Applications are invited for the following courses:

Mechanical and Electrical Engineering, Textiles, Chemistry, Colour Chemistry, Chemical Engineering and Chemical Technology, Dyeing, Commerce, Art, Architecture, Mathematics, Physics, Biology, Building, Music, Humanities, Domestic Science and Catering.

Full-time and Sandwich degrees and diploma courses, including diploma in technology in dyeing and in chemical technology.

The prospectus and further details can be obtained from the Registrar.

H. GRAY,
Clerk to the Governors.

COLLEGE OF TECHNOLOGY

BIRMINGHAM
DEPARTMENT OF MATHEMATICS
FOUR YEAR SANDWICH COURSE IN TECHNOLOGICAL MATHEMATICS

This course, which leads to a Diploma in Technology, comprises study in Pure Mathematics, Applied Mathematics, Industrial Statistics and Numerical Methods, and of modern aids to computation. Applications are invited from students who possess the following minimum qualifications: Two Advanced Level subjects in the General Certificate of Education from Pure Mathematics, Applied Mathematics, Pure and Applied Mathematics, Mathematics and Theoretical Mechanics.

Application forms can be obtained from the Head of the Mathematics Department, College of Technology, Suffolk Street, and should be completed as soon as possible. Please quote " D."

CHELSEA COLLEGE OF SCIENCE AND TECHNOLOGY

MANRESA ROAD, S.W.3
DEPARTMENT OF CHEMISTRY
SESSION 1958-59
Head of Department: J. F. J. Dippy, D.Sc., F.R.I.C.

Recognized Day and Evening Courses leading to B.Sc. degrees (London, Internal), and the Graduateship and the Diploma (Food and Drugs) of the Royal Institute of Chemistry, commence on Monday, September 22, 1958. Various postgraduate courses are also available.

Full particulars on application to the Secretary.

CHELSEA COLLEGE OF SCIENCE AND TECHNOLOGY

DEPARTMENT OF CHEMISTRY
ANALYTICAL METHODS

A series of postgraduate lectures on more recent analytical techniques will be held during the Autumn Term on Tuesdays at 7 p.m., commencing on October 7, 1958. The topics will include spectroscopic methods, solvent extraction, square wave polarography, radio-activation, isotopic dilution, inorganic paper chromatography, silicate analysis, nuclear magnetic resonance and organic sub-micro analysis.

A leaflet giving full details, and an application form, may be obtained from the Head of the Chemistry Department, Chelsea College of Science and Technology, Manresa Road, London, S.W.3.

OFFICIAL APPOINTMENTS

UNIVERSITY COLLEGE HOSPITAL MEDICAL School. Student Technicians required in the Department of Bacteriology and Pathological Museum. Salary in accordance with the Whitley Council Scale.—Application should be made to the Secretary, University College Hospital Medical School, University Street, London, W.C.1.

UNIVERSITY OF LIVERPOOL

Applications are invited from candidates of Ph.D. standard with research experience in organic chemistry for a Post-doctoral Fellowship in the Department of Organic Chemistry, to undertake work on metabolites of marine micro-organisms. Tenure of the Fellowship, which will commence on October 1, 1958, or as soon as possible thereafter, will be for two years in the first instance and renewable for a third year. The salary scale will be £800 by £50 to £900 per annum.

Applications, including the names of two referees, should be received not later than August 16, 1958.

EASTERN REGIONAL HOSPITAL BOARD

SCOTLAND
REGIONAL PHYSICS DEPARTMENT

There are vacancies for two Physicists in this department which has been established recently in Dundee to serve the Eastern region. The work covers a wide range of applications of physics to medicine, and there is close co-operation with Queen's College, University of St. Andrews. It is hoped to make one appointment in the grade of Senior Physicist, and one in the Basic grade; for the Senior post relevant experience is essential. The salary scale for the Senior grade is £1,100 by £50 to £1,500. For new entrants to the Basic grade with first- or second-class honours the scale is £625 by £25 to £700, with increments for postgraduate experience, and after a probationary period of not less than two years, £800 by £35 (5) by £25 (1) to £1,000. The appointments are superannuable.

Applications, giving the names of two referees, to be lodged with the Secretary to the Board, 430 Blackness Road, Dundee.

UNIVERSITY OF SOUTHAMPTON

SIR ALAN COBHAM RESEARCH FELLOWSHIP IN AERONAUTICS

Applications are invited for the above newly-formed Fellowship. Salary £850 per annum with an additional amount available for equipment and travel. Tenure two or three years. The successful applicant will be required to carry out research in one of the following subjects: (1) Aircraft Noise and Structures; (2) Hypersonics; (3) Helicopter Vibrations; (4) Jet flap investigations; (5) Numerical methods applied to wing design. In addition to the above Fellowship, candidates will be considered for sponsored research assistantships working in any of the above research programmes. Salaries according to qualifications and experience.

Further particulars should be obtained from the Secretary and Registrar, to whom applications (six copies), giving age, full details of qualifications and experience and the names of two referees, should be sent within three weeks of the appearance of this advertisement.

D.S.I.R. WATER POLLUTION RESEARCH Laboratory, Stevenage, Herts, requires Inorganic or Physical Chemists as Assistant Experimental Officers for work on physico-chemical problems in the study and prevention of pollution of rivers. Two of the posts are for radio-chemical work. Qualifications: G.C.E. (Advanced) in chemistry and another science subject. Over age 22, pass degree, H.N.C. in chemistry or equivalent qualification generally expected. Salary, £370 (age 18) to £800 (men). Women slightly less. Five-day week.—Forms from Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting Ref. F.479/8A.

ROYAL MILITARY COLLEGE OF SCIENCE, Shrivenham, Berkshire, requires male Senior Lecturers or Lecturers in Mathematics (preferably applied Mathematics), Mechanical Engineering, Electrical Engineering, Radar and Telecommunications, Engineering Physics. Teaching is University level; good facilities for research. Qualifications: Appropriate first- or second-class honours degree. Teaching experience an advantage, and knowledge of application of subject to Service matters useful. Age: Minimum for Senior Lecturer (normally) 26, for Lecturer 21. Salary Senior Lecturer, £1,130 to £1,330; Lecturer, £595 to £1,050. Starting salary allows credit for approved postgraduate experience and National Service. Superannuable under F.S.S.U. with good prospects of permanency. Quarters in residential officers' mess for single men. Possibility of houses at economic rent after waiting period for married men. Particulars and forms from Ministry of Labour and National Service, Technical and Scientific Register (K) 26 King Street, London, S.W.1, quoting A262/8A. Closing date August 18, 1958.

UNIVERSITY OF TASMANIA

AUSTRALIA
DEPARTMENT OF MATHEMATICS

The University invites applications for the posts of Lecturer or Senior Lecturer, and Lecturer in Mathematics. The salary scales for Lecturers are Grade II, £A.1,450 by £A.60 to £A.1.630 per annum, Grade I, £A.1,630 by £A.60 to £A.2,050, and for Senior Lecturers, £A.2,150 by £A.60 to £A.2.510. Appointment to the first vacancy will be offered within the range for Lecturers, Grade I, or the range for Senior Lecturers, and to the second vacancy within the range for Lecturers Grade II or Grade I according to qualifications and experience. An allowance is made towards travelling expenses and housing assistance is available.

Further particulars and information as to the method of application may be obtained from the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1. The closing date for the receipt of applications, in Australia and London, is October 13, 1958.

UNIVERSITY OF LEEDS

SCHOOL OF CHEMISTRY

Applications are invited for appointments as (a) Assistant Lecturer in Inorganic and Structural Chemistry (Professor E. G. Cox, F.R.S.) and (b) Assistant Lecturer in Organic Chemistry (Professor B. Lythgoe, F.R.S.) at a salary within the range £700 to £850 a year, according to age, qualifications and experience.

Applications (three copies), stating date of birth, qualifications and experience, together with the names of three referees, should reach the Registrar, the University, Leeds, 2 (from whom further particulars may be obtained) not later than August 9, 1958.

FEDERATION OF MALAYA

FISH CULTURE RESEARCH STATION, MALACCA
FISH BIOLOGIST

to study breeding, growth, feeding habits and life history of fish of importance to fish culture. Candidates must have a good honours degree in natural science (zoology) with at least two years' suitable postgraduate training or experience. Appointment on probation to the Research Branch of Her Majesty's Overseas Civil Service with superannuation under the Overseas Superannuation Scheme or on contract/gratuity terms with a gratuity of £58 for each completed period of three months' satisfactory service. Salary in scale £828 to £1,117 per annum plus expatriation pay and cost of living allowance at Malayan Government rates. Free passages on appointment and leave for officer, wife and children up to five persons in all. Furnished quarters, when available, at low rental.

Apply, giving brief particulars, to Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.65/23/04.

HONOURS GRADUATE REQUIRED BY the Atomic Weapons Research Establishment, Aldermaston, Berks, for duty at Orfordness, Suffolk. To be a senior member of a team responsible for the design of air-borne telemetry equipment and associated ground stations, the organization and carrying out of flying trials on various types of weapons, and the analysis and evaluation of the results. There is ample scope for original design work. A first- or second-class honours degree or equivalent required and several years' experience in electronics or communications, and preferably also in airborne equipment design and pulse techniques. Experience in the design of subminiature airborne equipment, transistor circuits, and small packaging will be considered a distinct advantage. Salary: Senior Scientific Officer, £1,215 to £1,425 per annum; Scientific Officer, to be assessed according to qualifications and experience within the scale £645 to £1,120 per annum. Contributory superannuation scheme. A house, or assistance towards legal expenses on house purchase, will be available for married officers living beyond daily travelling distance.—Postcards for application forms to the Senior Recruitment Officer at A.W.R.E., Aldermaston, Berks. Please quote ref. 1845/34.

UNIVERSITY OF LONDON.—THE SENATE invite applications for the Readership in Fluid Mechanics tenable at the Imperial College of Science and Technology (salary scale £1,475 £1,775 to £2,150 a year plus £80 London allo ance).—Applications (ten copies), must be re not later than September 11, 1958, by the demic Registrar, University of London, Sena House, W.C.1, from whom further particula may be obtained.

CULCHETH

and HARROW

Laboratory research, by its nature, is always ahead of site construction. At the Research and Development Laboratories of the United Kingdom Atomic Energy Authority at Culcheth, for example, the scientists and technicians are today testing and specifying materials for nuclear power projects which have not yet come off the drawing boards.

At the service of U.K.A.E.A. scientists — and of all engaged in nuclear engineering — are the facilities of the Kodak Laboratories at Harrow. Here more than 200 qualified scientists, with specialists on every side of photographic and radiographic inspection, are constantly at work serving their fellow scientists and engineers.

If there is any aspect of scientific photography or radiography on which you would like advice and information, please write to

Kodak LIMITED
INDUSTRIAL SALES DIVISION
Kodak House, Kingsway, London, W.C.2

THE CHIEF APPLICATION of photography at the U.K.A.E.A. laboratories at Culcheth is in recording details of apparatus, specimens, and metallurgical structures for later use in technical reports.

Photomicrography is employed extensively, the main uses being in studies of the grain size and structure of proposed canning materials and of possible uranium-based fuels before and after mechanical tests and in various conditions of heat treatment. Photomicrography is also used in studies of modes of deformation of uranium. Optical and electron micrograph investigations are made of structural changes in potential pressure vessel steels.

Time-lapse cinematography is used to record the sequence of dimensional changes during the thermal cycling of uranium.

Photographic methods are used to record diffracted x-radiation during the study of crystal structures.

AUTOMATIC TITRATIONS

ARE easily carried out by the E.I.L. Automatic Titrimeter, Model 24. This instrument is fully automatic, switching itself off on reaching the pre-set end point.

Either the volumetric or the coulometric method may be used, and separate titration units for each type are available. Duplicated connections are provided on the Control unit.

The endpoint setting dial is calibrated in pH and in millivolts, and the equipment can be used for any type of chemical reaction producing a determinate change of e.m.f. The accuracy of titration is 0.05 c.c. in 50 c.c.

INVENTION AND RESEARCH

THE report which Prof. C. F. Carter and Prof. B. R. Williams prepared last year on behalf of the British Association was concerned with the factors which determine the speed of application of science, and it laid stress on the importance of a favourable environment. Competition alone was not regarded as a sufficient condition for technical progress ; there must also be provision for fundamental research as well as for industrial research, and adequate educational provision for the training of technologists. Apart, however, from a glance at the patent system, which suggested that the bias of the patent system is towards the disclosure and use of inventions rather than their concealment or suppression, the report was not concerned with the origin of inventions and whether the industrial and social framework to-day was such as to stimulate a free flow of inventive genius and the functioning of creative minds.

The latter could be described as the main theme of a subsequent book by Prof. J. Jewkes, D. Sawyers and R. Stillerman[*]. It is not so much concerned with the origin of ideas, the functioning of the creative mind, or even with the elements of design and chance in discovery and invention, except in so far as these are affected by the system in which they function. What it really seeks to examine is the place of the individual in industrial society to-day, and whether the forms which the organization of research and development commonly takes have been beneficial or otherwise to inventive work, or whether the ostensible advantages of team-work and large-scale organization have been offset in some tangible or intangible way. To that extent the book overlaps some of the discussion in the symposium on "The Direction of Research Establishments" held at the National Physical Laboratory in September 1956[†].

Clearly, the most effective use of scientific and technical man-power demands that we should be clear as to the essential conditions required, just as our industrial efficiency requires that organization should be appropriate to serve those and other needs. It is important that, as this book suggests, the way this or that policy may influence the flow of invention should be considered, and the development of a European Free Trade Area could well give a keener interest in studies in a field of which we know relatively little, though whether ignorance is quite as profound as is here asserted might be questioned. Any necessary connexion between the growth of scientific knowledge and that of technology and invention is not easy to trace, and the need for more actual knowledge about technical and economic change is undeniable. A community, for example, seeking to encourage innovation has little guidance as to how best to proceed, what institutional framework will most effectively stimulate and encourage the men with powers of originality, most rapidly distinguish between the channels open to progress and the blind alleys, and most thoroughly reap the economic harvest from innovation.

Prof. Jewkes and his colleagues do not go very deeply into the problem which confronts every society of how to balance continuity and stability with change and receptivity to new ideas. It is with a comparatively limited aspect of technological change that they are concerned ; but they make the fair comment that industrial societies have shown little originality or ingenuity in creating institutions to ensure that all new ideas are caught and nothing lost, and have also not been prolific in devising institutions to encourage invention, though the patent system has been challenged more often than this book would suggest. Again, the decision which every society makes about the proportion of its resources to be devoted to research and invention involves fundamental questions about the ends for which society should strive ; and even if it could be shown that invention is to any significant extent a calculable, predictable element which could be embodied into the conscious planning of social and economic activity, that decision is unlikely to be appreciably affected by knowledge of the circumstances in which industrial innovations have arisen in modern times, and of any important changes in their sources between the present and the past century.

Accepting the distinction drawn here between invention and development, with which the book is only to a limited extent concerned—although as in all technology the criteria of achievement in invention is applied ultimately by the user and not, as in science, by the scientist—invention still stands nearer to science than to technology in the development sense. This study of factors which stimulate inventiveness is accordingly of deep interest to all concerned with the conditions which promote creative thinking and with the genesis of ideas. Moreover, if we can answer the questions which the authors put to us, we have still far to go to solve the major problems of development and overcome the difficulties and weaknesses in industry, and in government, to which Prof. Carter and Prof. Williams directed attention. In spite of casual remarks which display the bearing of such societies as the Lunar Society and the Manchester Literary and Philosophical Society on the intermingling of the scientists and technologists of the day, nothing like enough stress is laid upon the importance both to science and to technology of free communication. To provide for such intercourse and mingling and to establish the conditions in which knowledge and criticism are freely exchanged appears to be the vital first step; and when this is secured, the question of the individual or the research team appears to be relatively unimportant.

---

[*] The Sources of Invention. By John Jewkes, David Sawers and Richard Stillerman. Pp. xii+428. (London: Macmillan and Co., Ltd.; New York: St. Martin's Press, Inc., 1958.) 31s. 6d. net.

[†] The Direction of Research Establishments: Proceedings of a Symposium held at the National Physical Laboratory on 26th, 27th and 28th September, 1956. Pp. vi+422. (London: H.M. Stationery Office, 1957.) 25s. net. See also *Nature*, 178, 964 (1956).

What deserves more attention than it receives, and could receive, in this inquiry is the improvement of such communications. Scientific and technical literature is indeed extensive, but it is scarcely so easily and cheaply obtained as this book suggests, and some of the conditions which make it less accessible and more expensive are an indirect result of Government policy. So too, while those who are not employed in scientific and technical institutions but are frequently connected with scientific societies and institutions may also derive aid from industrial research associations or government research associations, it should be remembered that it is Government policy which has frustrated the project for a Science Centre in London and also, through the recent change in rating policy, jeopardized the existence of numerous scientific societies.

While it could not be argued that, in general, extensive and detailed records of scientific and technical knowledge are denied to the independent worker of calibre and purpose, it could certainly be shown that Government policy over the past ten years has made the dissemination and discussion of such knowledge more difficult, both for the individual and for the member of a research team. What stands out above all from this study is that the real danger to invention and to creative work arises from the multiplicity of such neglect on the part of the administrator. There is little more evidence to be found for the view that the day of the individual inventor is done or that effective prediction of inventions is possible; the real dangers in team-work arise when attempts are made to organize research in the same way that manufacture is organized and the conditions in which research is most effective are ignored. Even team-work in research is the result of the co-operation of individuals working under conditions which allow full-play to their individuality in pursuit of the common goal.

When all allowance is made for the tendency, due to the growing cost of equipment, for research to become a matter for institutions rather than individuals, any dangers inherent in the consequent increased scale of research departments may be offset by the greater opportunities which such institutions can offer for the bringing together of workers in different disciplines. The importance of such cross-fertilization of minds was well brought out in the last annual report from the President of the Carnegie Institution of Washington; but there is a further point which needs to be emphasized, and that is the value of a diversity of institutions. That is important as helping to offset the danger that any one type of institution may become rigid and over-organized; it also meets the problem of helping the individual inventor, whose very originality often makes him difficult to fit into a particular type of organization.

No serious attempt to further inventiveness can fail to take account of those qualities which characterize most inventors, whether they work inside or outside an institution, and which also have something in common with the characteristics of the research worker. To both of them assistance must be given largely on their own terms, and in a way that does not frustrate or destroy originality and initiative; yet it is probably true that this has been—and is—widely neglected. Nevertheless, the influence of that factor alone may well outweigh that of size and organization as such. Whether or not the inventive ability of the community is being increasingly absorbed into organized research institutions, that of itself need not imply that inventors are less free to pursue their own ideas. It is not necessarily a disadvantage that they are less dependent on their own resources, nor is there any evidence that if they are less directly the recipients of the gains to be made from their inventions they are in consequence likely to be less inventive.

Broadly speaking, however, the bias of Prof. Jewkes and his colleagues appears to be against the view that the inventive ability of the community can only be put to the best use if it is increasingly set to work in organized research institutions. In challenging the belief that the day of the individual inventor has gone, they appear to swing too far against the research institution or department. There will always be individuals who will not fit into an organization, and it is important that society should make due provision for such lone individuals or eccentrics. The growing importance of the inventor with a professional training in science and technology is not likely to eliminate this factor, though it may simplify the problem of helping him.

Whether as much importance can be attached to the numerical incidence of inventions within or without the main research institutions or centres is, however, doubtful. If the prediction of invention is difficult, the identification of inventive talent before it has manifested itself is no less impracticable, and unless that is possible the element of chance may well vitiate all the numerical comparisons. The important thing is to see that the inescapable coordination and administration, both in industry and in society as a whole, are as dynamic and creative as possible, and to provide the framework within which the individual can express fully his creative and inventive powers.

Apart from this, the picture of large and small industrial laboratories presented as essentially authoritarian and mediocre bodies is open to challenge. Many of them are far from lacking the atmosphere necessary for creative work, and the discussion on creative work at the symposium on the direction of research establishments already referred to indicates that managers are often fully alive to the significance of such factors. Prof. D. J. van Lennep suggested, in fact, that creative research workers are less dependent upon their environment, less rigid and less dogmatic, as well as marked by a characteristic time perspective, perceiving the future as fraught with possibilities which they themselves could help to realize. Prof. M. I. Stein, from a study at the University of Chicago of factors influencing the creativity of industrial research chemists, suggested that creativity is a result of social environment and processes occurring within the individual; in his view, although we need more knowledge of the way in which environment affects a man's creative powers and of what psychological factors, in a satisfactory environment, stimulate creativity, adequate equipment, a congenial intellectual society and the secure livelihood which the research institution provides are to-day vital requirements for creative activity. Without them the essential tranquillity and concentration on the problem in hand are scarcely possible.

The discussion at the National Physical Laboratory rather than that of Prof. Jewkes and his colleagues seems to point the right way and to identify the problems that require examination. Whether science is playing a greater part in invention and whether inventions are due more to accidental discoveries than to rational planning and research seem to be of secondary importance. Even if the big corporations and research teams are replacing the lone inventor with limited resources, we still need to give much fuller attention to the conditions which foster creative work and invention. It is true that as one aspect it should be considered whether the growth in the scale of invention and development, of government-sponsored research and even changes in university education may tend to diminish invention by increasing resistance to change; quite rightly attention is directed to the value of the uncommitted mind and of the way the grooves of accepted thought may hinder invention. We need, however, to know more about the optimum size of research groups, the way a group functions in developing ideas, and of the effect on such a group and on himself of a really gifted individual.

We have already a good deal of information, of which the Government seems to be unaware, which if acted upon could minimize or eliminate the major dangers to which Jewkes *et al.* direct attention. It is already recognized that research establishments, industrial or academic, can never be too vigilant in fostering original thought; but we could probably make fuller use of the known techniques of selection to place those with creative talents in places where they have the most adequate opportunity of expression. Moreover, the tendency of modern management to become catalytic rather than directive is also in line with what is demanded in the most effective use of creative and inventive talent.

It is in such ways as these that the sources of invention can be kept free and unblocked, and it should be noted that in this whole process the improvement of communications plays a vital part. This is not simply an educational issue, though the development of technological and technical as well as university education could contribute much to a surge of understanding that would increase our ability to encourage and utilize the outflow of creative ideas. It is also a matter of administrative action and improving conditions in a field to which successive Governments have hitherto been indifferent.

That seems to be one of the ways in which immediate action could be taken, and in raising the question of the rating of scientific societies, the opportunity should be used to bring home to the Government the vital contribution which such societies still make to the communication of knowledge and the stimulation of ideas. Attention should be directed, too, to their part in publication, to the handicap which postal charges now place on such undertakings, to the urgent need for an adequate national policy for scientific and technical libraries, and to the practical value of a National Science Centre. Much could be done in ways such as these, while Prof. M. I. Stein and Prof. D. J. van Lennep pursue their studies at the Universities of Chicago and Utrecht. Meanwhile, Prof. Jewkes *et al.* have indicated further questions to which answers could well be sought; but the doubts he expresses as to the teamwork appear to be sufficiently answered by Prof. René Taton, approaching the subject from an entirely different angle in a fascinating essay, "Design and Chance in Discovery and Invention", published in *Impact* (Paris: Unesco) some two years ago. The dangers lie, in fact, not so much in the institution as in the way it is used, and the further knowledge continually being gathered as to how to use our institutions could well offset any increasing difficulty for the independent individual to exercise his inventive faculty, which Prof. J. D. Bernal believes is inherent in the nature of modern industry.

FROM DIVINE TO CONTINUOUS CREATION

Theories of the Universe from Babylonian Myth to Modern Science

Edited by Milton K. Munitz. (The Library of Scientific Thought.) Pp. x+437. (Glencoe, Ill.: The Free Press; Indian Hills, Colorado: The Falcon's Wing Press; London: George Allen and Unwin, Ltd., 1957.) 48*s.* net.

WITH the multiplication of courses on the history of science there has come from publishers an increasing and welcome flow of source-books and translations of all kinds, particularly of trans-Atlantic origin. For example, the McGraw-Hill series of 'readings' from classic originals in mathematics, physics, chemistry and so on has been widely known and used. Now Mr. Milton K. Munitz, of New York University, has had the excellent notion of producing a similar set of 'readings' to illustrate the evolution of cosmological theories. In his volume the extracts are somewhat longer and more complete than in some of its predecessors—a point in its favour; and he has not chosen from among contemporary sources only, but has reprinted passages from recent historians and expositors. This seems a less satisfactory innovation. The works of writers like Cornford, Dreyer or Francis

Johnson can rarely be so very inaccessible to students or even to the general reader; and the inclusion of the interpretation of some historical phase by a single scholar in a collection of this kind, however eminently enlightening his views may be, is likely to set a stamp of infallibility upon them. In Mr. Munitz's book the only pieces on the period between Ptolemy and Copernicus are twenty-four pages from Dreyer's well-known history of planetary theories (available for some time in a cheap reprint) and an extract of three pages from Nicholas of Cusa's "De docta ignorantia". Dreyer was a learned and careful writer; but he wrote of almost everything medieval in terms of contempt, and the section here reprinted concludes with Dante. It would have been more just to contrast the primitive conceptions of some medieval Christians with the rational and open discussions of such a philosopher as Oresme in the fourteenth century. Medieval philosophers had more serious problems than the calculation of the number of angels who could dance on a needle-point; medieval cosmologists had more serious problems than determining the site of heaven and hell—though it is unclear why this should not be a matter of interest to a professed Christian.

The choice of authors in an anthology like this is virtually dictated, and proceeds (as the sub-title indicates) from Jacobsen's account of Babylonian creation-myths through the Ionians, the famous later Greeks, Copernicus, Galileo, Newton, Herschel and others to a relatively much more ample extraction from the modern cosmologists—Willem de Sitter to Fred Hoyle. To these last more than a third of the whole book is devoted. Within the range of authors an anthologist has a freer choice: Mr. Munitz has usually, though not invariably, hit upon passages that contain the kernel of a conception. His Lucretius is fascinating; his Ptolemy demonstrates the obvious fact that Ptolemy was great as a technical astronomer, not as a creative thinker; his Galileo, unfortunately, is rather dull—a statement of the Copernican system, certainly, but not an introduction to the intellectual exhilaration of Galileo's writings, nor indicative of his great cosmological theme, that the universe is a system of physically similar bodies, subject to the same physical laws. It was a pity to omit Descartes, for his idea of the universe changing in time. Again, the passages taken from Newton are well worthy of study, including the four letters to Bentley; yet one misses inevitably the foundation of exact science that underlay Newton's wider (and more vulnerable) ideas, and that constitutes the solidity of the "Principia". It is indeed difficult to see how cosmological theories can be presented in manageable form along with their necessary substratum in the observable facts of astronomy and astrophysics; but it is by its relation to the available substratum of science that any theory of the universe must be judged as a contribution to the intellectual development of its time.

One cannot say that there is much here that is not accessible fairly readily and in English; nevertheless, it is valuable to have typical passages reprinted, and the close juxtaposition of conflicting arguments is highly stimulating. The collection will be a convenient introduction to one area of controlled speculation which has always furnished a major theme in the growth of science. As such, it is worthy to stand by others of the same kind as a volume to which both teachers and students will often turn with profit.

A. R. Hall

NICOLAUS STENO

Nicolaus Steno and His Indice

Edited by Gustav Scherz. (*Acta Historica Scientiarum Naturalium et Medicinalium*, Vol. 15.) Pp. 314. (Copenhagen: Ejnar Munksgaard, 1958.) 32 Danish Kr.

The life of Nicolaus Steno (1638–86) falls, broadly speaking, into two periods, the scientific (to 1674) and the priestly. A notable figure among the many great scientists of that formative period, the seventeenth century, Steno made important contributions to human and comparative anatomy, embryology, geology and palæontology; and his studies of crystals of quartz have earned him the title of 'Father of Crystallography'.

In this small volume, a concise biography by G. Scherz is followed by essays by six other contributors: "Nicolaus Steno's Contribution to Zoology", by Ragnar Spärck; "Nicolas Sténon Paléontologiste", by Rémacle Rome; "Nicolaus Steno and Scientific Geology", by Axel Garboe; "Niels Stensen und die Kristallographie", by Heinrich Tertsch; "Niels Stensen und der Cartesianismus", by Adolf Faller; and "The Influence of Nicolaus Steno on the Development of Geological Science in Britain", by V. A. Eyles.

The essays by Dr. Garboe and Fr. Rome trace the development of Steno's notions of geological strata and his conviction that fossils are indeed the remains of living animals. These ideas, and similar ideas developed independently by Robert Hooke, led to a long-drawn-out argument over the origin of fossils; Dr. Eyles reviews the beginnings of this controversy, with particular reference to the independence of Hooke's and Steno's work and to the continued appreciation and citation of Steno's arguments by British scientists when they were forgotten over much of Europe.

Of Steno's pioneer work in crystallography, his discovery of the constancy of crystal angles throughout all variations of habit is well known, but it is less generally realized that his studies of ghost quartz and of zoned inclusions led him to conclude that crystals grow, and grow by apposition of new layers on the several faces, a very different mode of growth from that of living beings; he noted that the rate of accretion varies on faces belonging, in modern terms, to different forms, and endeavoured to account for the striations on the prism faces of quartz, and the tendency to a tapered prismatic habit. Dr. Tertsch gives an excellent review of Steno's work on quartz, pyrite and hæmatite crystals, and points out that Steno's measurements were not wholly interfacial angles as is commonly assumed; some at least were interzonal (inter-edge) measurements.

Steno's scientific work was largely based on two collections of natural objects, his own and that of the Grand Duke, which are known to have been housed in Florence; it is probable that some at least of this material still survives, though none can now be traced with certainty. But copies of a catalogue exist that was almost certainly originally written or dictated by Steno; the descriptions of crystals, minerals and fossils in this catalogue are of great interest, and it forms one of the most useful features of this book. Dr. Schertz has collated and reprinted the Italian text with an English translation and with extensive and valuable notes.

M. H. Hey

PHARMACOPŒIAS AND FORMULARIES

British Pharmacopœia 1958

Pp. xxvi+1012. (London: The Pharmaceutical Press, 1958. Published for the General Medical Council.) 63*s*. net.

British National Formulary, 1957

Pp. 226. (London: British Medical Association; and the Pharmaceutical Society of Great Britain, 1957.) Standard edition 6*s*. 6*d*.; Interleaved edition 10*s*.

British National Formulary, 1957

Alternative edition based on a Pharmacological Classification. Pp. 245. (London: British Medical Association; and the Pharmaceutical Society of Great Britain, 1957.) 7*s*. 6*d*.; Interleaved edition, 10*s*. 6*d*.

The Extra Pharmacopœia

Vol. 1 (Martindale). Twenty-fourth edition. Pp. xxx+1695. (London: The Pharmaceutical Press, 1958.) 65*s*.

IT is a hundred years since the General Medical Council became responsible for publishing "The British Pharmacopœia". The present issue is the ninth since that date and it becomes official from September 1 when the standards laid down for the medicaments included will be legally enforceable and supersede those of the eighth edition of 1953 and its addendum of 1956. The work of selecting drugs for inclusion in "The Pharmacopœia" and of setting standards for them is delegated to the British Pharmacopœial Commission assisted by expert committees, and it is the present intention that a new edition should be produced every five years. Each succeeding issue marks the trend of medical practice from the empiricism of the nineteenth century (dependent mainly on natural products for drugs) towards the physician's ideal of using pure substances of known and precise pharmacological action. Belladonna root, mercury ointment and quassia are well known substances which at last, with 135 other items, have fallen from official favour to make way for 160 new monographs, including such names as acetazolamide, prednisolone, and tetracycline hydrochloride. It is interesting to note that phenylbutazone, which was considered sufficiently well established as a therapeutic agent to be included in the 1956 addendum, is deleted in this edition, presumably because of adverse clinical reports about it in the past two years. For the first time radioactive materials, the sodium salts of radioiodine-131 and of radiophosphorus-32 appear as monographs.

The break with tradition, begun in 1953, of using English titles for monographs instead of Latin headings has continued, and in this issue many of the English titles have been simplified. However, many modern medicaments are produced under registered trade marks and patents held by individual firms which give their products names different from those selected by the Commission. To aid those in medical and pharmaceutical practice to identify brands of official medicaments, the Commission has authorized the publication of a pamphlet, listing approved names and the other names by which a medicament may be known, for use in conjunction with the new pharmacopœia.

Standards for drugs and medicaments naturally become more exacting and complex with each succeeding issue of "The British Pharmacopœia" and must of necessity refer to equally important standards of other official bodies. Close collaboration between such bodies is to be expected and it is disappointing to find that determinations of viscosity are based on apparatus described in British Standard 188 of 1937 instead of the current issue of 1957. Apart from this lapse I have great admiration for the general quality of the latest publication. The Commission and especially the editor are unreservedly to be congratulated on a fine production.

Similar congratulations should be extended to the Joint Formulary Committee for producing "The British National Formulary, 1957". This is the fourth edition of what has hitherto been known as the "National Formulary", the change in title being introduced to avoid confusion with the United States book of standards of the same name. Whereas "The British Pharmacopœia" is primarily a collection of specifications for drugs and is to be found on the manufacturer's and analyst's bookshelves rather than in the consulting room, "The British National Formulary" is the constant companion of every physician and pharmacist in general practice. The standard edition follows the traditional pattern for this pocket-book, containing notes for prescribers, useful information on the treatment of poisoning and identification of medical gas cylinders, as well as the formulary of medicaments set out in pharmaceutical types (mixtures, injections, eye-lotions, tablets, etc.). This classification, however, while of great use to the pharmacist, can be inconvenient for the prescriber who thinks of his medicaments in terms of the action that they will produce. To meet this situation an alternative edition has been issued based on a pharmacological classification, with added comments on the use and reactions of the drugs listed in the standard edition.

However useful the pharmacological edition of "The British National Formulary" may be, it must of necessity remain a pocket-book, limiting the scope and the amount of information which can be incorporated. The need for a comprehensive reference book giving medical and pharmaceutical information on the majority of medicaments in present use is obvious. This need has been filled for many years by "Martindale's Extra Pharmacopœia", which first appeared in 1883 as one volume. Such has been the progress of medical knowledge that by the fifteenth edition in 1911 the information to be incorporated required the work to be split into two parts, Vol. 1 being devoted to the medical and pharmaceutical properties of medicaments and Vol. 2 to descriptions of ancillary subjects such as analytical standards, hæmatology, sterilization and disinfection, etc. The twenty-fourth edition of Vol. 1 is completely rewritten and is probably the most useful work of reference available in this field to-day. The keys to the book are the general index containing nearly 20,000 entries and the therapeutic index indicating possible treatment for nearly 800 medical conditions. I noted with pleasure that although "Martindale" was published only one month after "The British Pharmacopœia 1958", the co-operation between those responsible for the two books has been such that the main changes introduced by the official standard are indicated in a special section (and, more important, in the index) of the "Extra Pharmacopœia". In addition, twenty-four other pharmacopœias and related publications from all over the world have been examined and relevant material noted. Careful editing has been necessary in the selection of abstracts referring to specific-substances and this has been admirably executed. This book is an essential part of the libraries of all who are connected or interested in any way whatsoever with medicine and pharmacy.

DAVID TRAIN

SOCIAL CHANGE IN SIMPLER SOCIETIES

Yulengor

Nomads of Arnhem Land. By Wilbur S. Chaseling. Pp. xxvi+173+13 plates. (London: The Epworth Press, 1957.) 21*s*. net.

Easter Island

A Stone-Age Civilization of the Pacific. By Dr. Alfred Metraux. (Translated from the French by Michael Bullock.) Pp. 249+16 plates. (London: Andre Deutsch, Ltd., 1957.) 21*s*. net.

Work and Life on Raroia

An Acculturation Study from the Tuamotu Group, French Oceania. By Dr. Bengt Danielsson. Pp. 244+7 plates. (London: George Allen and Unwin, Ltd., 1956.) 25*s*. net.

Social Change in the South Pacific

Rarotonga and Aitutaki. By Prof. Ernest Beaglehole. Pp. x+268. (London: George Allen and Unwin, Ltd., 1957.) 28*s*. net.

THE theoretical and the practical importance of the social changes that have been taking place in the technologically undeveloped communities have led to the production of many books on the subject in recent years. These four works deal with the results of Westernization on indigenous peoples in Polynesia and in Northern Australia. Three of them, concerned with agricultural Polynesian communities, are by professional anthropologists; one, on the Arnhem Land nomads, is by a layman.

"Yulengor"—the name is the East Arnhem Land equivalent for aboriginal nomads—has been written by a missionary of long experience in the region. He landed there in 1934, and the results of his close sympathetic observation over a number of years make extremely interesting reading. He describes the domestic life, the hunting and collecting economy of these still primitive people, their initiation, burial and other rituals, their magic, their creation myths. The treatment is not very systematic, but a useful introduction by Prof. A. P. Elkin supplies the framework of the aboriginal social structure. The picture presented is one of extreme simplicity of life. Mr. W. S. Chaseling states that "the daily life of the people has not changed in a thousand decades and still involves hunting with stone and wooden spears and stone axes for everything the nomad eats". But he also says that metal has been filtering into the country for two centuries, and this has made hunting for sea-animals—such as turtle and dugong—easier. Again, nearly all the people in his photographs wear a modicum of clothing. This and other evidence indicates what anthropologists are by now well aware of, that even here the primitive Australian has undergone considerable change in his mode of life through foreign contact.

Dr. A. Metraux's book is a craftsman's job. Easter Island has provided one of the popular mysteries of the world and, as Dr. Metraux says, many audacious solutions to its problems have been provided. He himself gives an admirably clear, sober outline of the whole situation. He describes the traditional culture of the islanders and the radical, often tragic, changes that the community has undergone since Europeans first called there. He indicates the problems of origin and function connected with the cultural remnants now left to us. He does not shirk the difficulties of the problems. In particular, his own interpretation of the mnemonic and symbolic function of the wooden tablets "carved with script" is given as definitely provisional. He is equally critical and firm about the various theories put forward by others about the origins of Easter Island civilization in external sources. His own conclusion, that Easter Island sculpture, including the great statues, represents a specialization of Polynesian culture—probably from a Marquesan source—favoured by particularly local conditions, is one which has strong anthropological support. The book is a condensation and revision of an earlier scientific monograph, and while primarily for the non-specialized reader, may be taken as an authoritative statement.

In "Work and Life on Raroia", Dr. B. Danielsson continues in scientific vein his study of the Tuamotu Island community among whom he landed, in company with his companions of the Kon-Tiki raft, in 1947. This study of the social and economic condition of the community of rather more than a hundred persons is very detailed and one of the most useful accounts of a Polynesian island economy which we possess. The author studied the modes of production, both for subsistence and for cash exchange, the land tenure, and the income and expenditure patterns of the people. He prefaces his analysis by a detailed examination of the demographic condition and of the history of their contacts with other cultures. The changes in the society have been considerable. Apart from concentration of residence in a single village, there has been a decrease in the size of kin groups, a high degree of individualization of work as a result of the introduction of a competitive money economy, and a breakdown of the former system of hierarchical authority. Surprisingly for Polynesia, a man who wants to build a house must pay the workers in money, at wages almost as high as in Tahiti. For such a small population, the analysis of the figures is perhaps over-elaborate and the data on social structure too thin. But as the author points out, so far very few anthropological studies have been made of modern Polynesian communities showing the ways in which individuals and groups have responded to the varying local conditions of contact. This work is a very useful contribution to the study of acculturation process in the Pacific.

The study of Rarotonga and Aitutaki by Prof. E. Beaglehole is of a much broader character—indeed, its title goes much further than its content. The author has had a great deal of experience in studying Polynesian communities already, and the results of this emerge in his penetrating analysis and comprehensive generalizations. He has supplemented the limited amount of field research he was able to manage with a careful examination of the historical records. Using both an anthropological and a psychological frame of reference, he has given a valuable study of the history of social change in these two communities. He has also suggested a typology for such change and singled out clearly the various major factors in the process. Much of his analysis is concerned with the part played by missionary and Government official in the island communities, but a very substantial part of the book covers their demography, their economy and their social structure. A concluding section relates his findings to the administrative problems of development and welfare that now urgently concern the New Zealand Government, which has the responsibility for care of these islands.

All these works are worth reading for their sincerity and insight into an important aspect of modern social process. RAYMOND FIRTH

A COMPREHENSIVE HANDBOOK ON THE CARE OF LABORATORY ANIMALS

The UFAW Handbook on the Care and Management of Laboratory Animals

Edited by Alastair N. Worden and W. Lane-Petter. Second edition, greatly enlarged. Pp. xix+951. (London: Universities Federation for Animal Welfare, 1957.) 70*s.* net.

EVERY scientist who uses laboratory animals should realize the importance of good stock husbandry. Technical, as well as humane, considerations demand that experimental animals be kept under the best possible conditions, for environmental irregularities can confuse experimental results. This publication contains a wealth of knowledge on the management of nearly all the species of animals used in laboratories, and can be used as a guide to their respective needs by any worker who is seeking detailed information. This second edition is far more extensive than the first, and the additional matter included comprises not only knowledge acquired during the past ten years, but also details of additional species. More than eighty recognized authorities have contributed, for each chapter has been prepared by a worker who is an expert on the subject with which it deals.

The first part of the book is devoted to general considerations which apply to nearly all species. Subjects covered include the legal protection of laboratory animals, the designing and equipping of animal houses, the principles of hygiene, breeding methods, feeding, handling, anæsthesia and euthanasia.

The second part is devoted to comprehensive accounts of the many different species which are used for experimental work, and more than fifty species are dealt with individually. This part is subdivided on the basis of zoological classification. The first group deals with the rodents and lagomorphs, including the guinea pig, the rabbit, and various species of voles, rats, mice and hamsters. The shrews and hedgehogs, which are insectivores, are next described. The carnivores, such as the cat, dog, fox, ferret, mink and marten, follow. The ungulates, including the sheep, goat, horse and pig, form another group, and in small groups on their own are the primates and marsupials. Among the bird species included are the fowl, pigeon and canary. Other groups covered are the reptiles, amphibia and fish, and a miscellaneous group of invertebrates. Finally, some notes are given on more than twenty other species not dealt with in detail.

The information on each species is clearly set out, and most chapters contain information on accommodation, feeding, breeding, handling and disease control. A comprehensive list of references is given at the end of each chapter. The amount of space devoted to each species has been carefully controlled, and a well-balanced book has resulted. There is both a subject and an author index. The book is illustrated by clear photographs and diagrams dealing particularly with various types of cages and equipment.

This book will undoubtedly be widely read by scientific workers who use experimental animals, and could, with advantage, be provided as a standard reference book in all institutes where laboratory animals are kept. The contributors are to be congratulated on the way in which they have recorded the knowledge they have acquired by experience, and a debt of gratitude is due to the Universities Federation of Animal Welfare for producing this book, which will do so much to make this knowledge readily available to all who use or tend laboratory animals.

J. O. L. KING

MAN-ANIMAL RELATIONSHIPS

Tuberculosis in Animals and Man

A Study in Comparative Pathology. By Prof. John Francis. Pp. xvi+357+40 plates. (London: Cassell and Co., Ltd., 1958.) 105*s.* net.

PROF. FRANCIS has collected within the covers of one volume a vast amount of information on tuberculosis in both animals and man, gleaned from sources in all parts of the world. At this time when the elimination of tuberculosis from cattle in Great Britain is progressing rapidly and the time is within sight when the disease will disappear altogether from our herds, it is helpful to have before one this large volume of information of the disease in other species, including man, since these reservoirs of infection could well prove a menace to the maintenance of disease-free herds.

The earlier chapters of the book, which deal with the pathogenesis and pathology of bovine tuberculosis and the control of this disease in cattle, are by no means outdated by the fact that the disease in cattle may soon disappear from Great Britain; indeed, if it is to be prevented from re-establishing itself among our herds a sound knowledge of its pathology and epidemiology is essential.

Prof. Francis deals with the disease in monkeys, guinea pigs, rabbits, voles, elephants, buffaloes, all farm animals (including poultry, dogs and cats), camels, mink and silver foxes, rats and mice, wild animals, ferrets, hamsters, birds and finally cold-blooded animals. At the end of each section of the book the author presents a complete list of references so that the reader can refer to the origin of information dealing with the disease in each separate species of animals. As most of the information contained in the book is factual and supported by clear references, the work invites little or no challenge of opinion. Even so, where the author does draw deductions from the information which he has gathered together, or offer opinions on the significance of the information available, he does so with commendable restraint and the reader will greatly appreciate the complete and objective impartiality with which the work has been compiled.

Illustrations, though not exceptionally profuse, are clear and truly illustrate what they are intended to portray. The author is to be congratulated on producing a work of the utmost interest and value to all who are interested not only in tuberculosis but also in comparative pathology in its widest sense.

This volume will be widely read and highly appreciated in both medical and veterinary circles throughout the world. HAROLD BURROW

CRYSTAL STRUCTURES

Structure Reports

Edited by A. J. C. Wilson. Vol. 8: 1940–1941. Pp. viii+384. 80 Dutch florins. Vol. 9: 1942–1944. Pp. viii+448. 65 Dutch florins. Vol. 15: 1951. Pp. vii+588. 110 Dutch florins. (Utrecht: N.V. A. Oosthoek's Uitgevers Mij, 1956 and 1957.)

THE possibility of considering more than one volume of "Structure Reports"—intended as an annual reference work—in a single review is proof of the welcome fact that the editors are fulfilling their promise not only to keep the series up to date, but also simultaneously to bridge the gap of the war years. This gap is now happily closed with the appearance of Vol. 8, which contains such classical work as the structure of melamine (in which mathematical refinement techniques now in general use were first introduced), the observation that diffuse scattering is a widespread and informative phenomenon, and the X-ray studies of the phthalocyanines.

In all three volumes, as usual, the coverage is excellent, the format acceptable, and the information admirably distilled. The series now forms an excellent starting-point for the systematic analysis of the fruits of some forty years of international endeavour involving the determination of many hundreds of crystal structures—organic, inorganic and metallic—by a variety of diffraction techniques, supplemented by such structural information as may be obtained from other disciplines like spectroscopy.

Published work has not been abstracted blindly. On the contrary, detailed assessments of each structure have been made, and critical comments are inserted by the editors where they have felt it necessary to do so. This critical analysis of published structures is a particularly valuable feature of the series. The vast amount of calculation necessary to extract the maximum information even from experimental data of only moderate quality makes it virtually certain that many published structures could be made to yield more accurate results than those with which one had to be satisfied before the advent of digital computers. On the other hand, high-speed computation allied with a failure to recognize the limitations of the data themselves merely permits us to reach a wrong answer faster than ever before.

Crystallographers generally are alive both to the potentialities and to the dangers of the present stage of development of the subject, and the standing of the editors in their own field is an adequate guarantee that non-crystallographers using these volumes will have the benefit of a sound assessment of the expanding stream of crystal structure analyses which look so impressive in the learned journals. Pondering the rapid increase in size and complexity of solvable structures, one is reminded of the optimistic advertisement—"the impossible we do at once; miracles take a little longer"; and miracles they truly are, for modern techniques are now carrying us, within the life-time of many of the original pioneers of X-ray crystallography, from the sort of crystals the structures of which a physicist can draw from memory to the sort of molecules which lie near the root of life itself. These volumes provide a worthy record of this continuing advance. It is a pity that their price makes them a luxury when their importance renders them a necessity. H. J. GRENVILLE-WELLS

METABOLISM OF THE NERVOUS SYSTEM

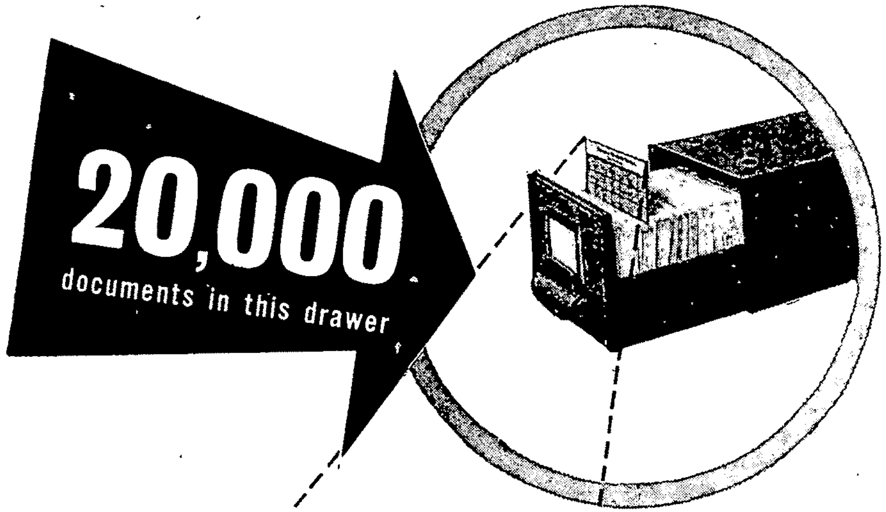
Metabolism of the Nervous System

Edited by Derek Richter. Pp. xiv+600. (London and New York: Pergamon Press, 1957.) 100s.

THE central nervous system provides more fascinating problems than any other part of the body and scientists all over the world are studying it from many points of view and travelling to meetings and symposia and congresses to discuss their results. These discussions often appear in book form and the present work is one of the most valuable of these books. It is based on the Second International Neurochemical Symposium, which was held at Aarhus, Denmark, in July 1956. It is divided into thirteen sections each dealing with a different aspect of the metabolism of the nervous system. Each section opens with a general review, which is followed by shorter and more specialized papers. There is so much that is valuable that it is impossible to mention more than a few examples of interesting contributions. There are some fine reproductions of pictures obtained with the electron microscope, there is a discussion by A. Engström of the use of X-rays to analyse structure, and a discussion of the blood-brain barrier, and various other barriers. R. D. Keynes discusses electrolytes, F. Brink discusses nerve metabolism, S. S. Kety discusses the metabolism of the brain as a whole and J. H. Quastel discusses the metabolism of tissue preparations of brain. O. H. Lowry describes experiments in which he dissects out single cells, weighs them and measures enzymes in them. As the total weight is often less than 0·01 μgm. this requires a rather special balance, but he hopes to extend his technique to single mitochondria.

R. V. Coxon, R. J. Rossiter, L. Einarson and H. Waelsch discuss the metabolism of carbohydrates, fats, nucleic acids and proteins respectively. W. Feldberg discusses acetylcholine, U.S. v. Euler and M. Vogt discuss noradrenaline, S. Udenfriend discusses 5-hydroxytryptamine and J. Crossland discusses all the other active substances which might possibly act as chemical transmitters.

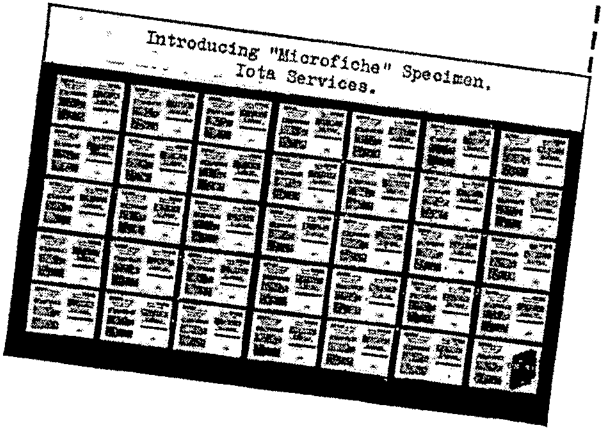
It will be seen that this book covers a wide field, but only a small proportion of the papers have been mentioned; there are well over fifty altogether. It is a valuable guide to the results obtained by many different methods written by the leading authorities. Many of the papers are followed by short discussions, which help those who were not there to form a judgment of their importance. The book is beautifully produced but expensive. Libraries will have to buy it; individuals working in this field will buy it if they can afford it. J. H. GADDUM



Microfiche

records them

on 5" x 3" cards!



. . . and only comparatively few cards are needed.

The newest, most convenient microfilming technique, MICROFICHE will record up to 32 pages (15 x 19 in.) on a single 5 x 3 in. transparent card.

Definition is perfect . . . each card is given a title of normal reading size during the photographic process.

Documents of all kinds, cheques, letters, memoranda and patents, books, magazines and newspapers are ideal subjects for preservation by MICROFICHE.

The process simplifies the transfer of typed and printed matter between offices, branches, companies. And, where postal charges are a consideration, it reduces the cost.

Write to IOTA for full information about MICROFICHE

UNITHERM DRIER

Designed on the same principle as a coupled heating and ventilating system, the Unitherm Drier is an efficient laboratory cabinet giving rapid, uniform drying.

It has a capacity of 100 trays of 400 grams of material of D.M. content 20% and has been carefully tested at controlled working temperatures up to 105° C.

Leaflet No. 24 gives full details.

AN INTERNATIONAL MILK TEETH RADIATION CENSUS

By Dr. HERMAN M. KALCKAR*

U.S. Department of Health, Education, and Welfare, Public Health Service, National Institutes of Health, National Institute of Arthritis and Metabolic Diseases, Bethesda, Maryland

WITHOUT expressing here any opinion concerning atomic weapons test programmes, I wish to suggest a scientific study which would at the same time have educational values in its practical demonstration of the peaceful applications of atomic research. The suggestion arises from the belief that any family, regardless of whether or not its country has ambitions in the development of atomic weapons, would be sympathetic to and support an international study involving atomic radiation and ultimately concerned with the health of its own children.

It is generally recognized that young children take up radioactive strontium and cæsium more intensely than adolescents and adults. It is most likely that they also have higher biological radiosensitivity, regardless of whether the dosage results from radioactive strontium, cæsium, iodine, or X-rays. Hence radiation hazards, both those stemming from the peaceful use of atomic power and those having to do with the military use of nuclear energy, must be recognized as being greater during early childhood. Moreover, modern biology has demonstrated the incidence in various human races of certain aberrations, such as defects in reductive metabolism. These considerations, together with the great need for precise knowledge of the biological factors involved, should be stressed to the general public and to all those whose informed participation would be essential to the success of the project to be described.

The official public health agencies of every nation, and especially of the British Commonwealth, China, India, the United States and the U.S.S.R., should organize a large-scale collection of milk teeth (with dates of appearance and shedding, and the child's age in each instance) and conduct measurements of radioactivity on this material. Thousands of countings, performed on a decentralized basis in individual communities and collected on a national basis, would be essential, both to ensure the validity of the results and to assure a widespread sense of active participation on the part of the people of many nations.

Such an International Milk Teeth Radiation Census would contribute important information concerning the amount and kind of radiation received by the most sensitive section of any population, namely, the children. At present, important although rather erratic data exist, based on autopsy of bone samples derived mainly from adults. If a study of a large-scale collection of deciduous teeth were to be initiated in order to confirm and extend these data, it would require an extensive technical organization, adequate equipment, and trained personnel.

Early work by Hevesy, Holst and Krogh[1], Armstrong[2] and Pedersen and Schmidt-Nielsen[3] made it clear that dental enamel takes up phosphorus-32 rapidly during its formation but does not significantly renew itself; dentine renews itself to a detectable degree but much more slowly than bone. Dr. Wallace Armstrong, University of Minnesota, and Dr. S. Kreshover, National Institute of Dental Research, directed my attention to the fact that measurements of radiation from deciduous incisor teeth would reflect the situation as it existed about seven years previously, namely, at birth or shortly before, when the calcified structure of the deciduous teeth is deposited. At present it would seem necessary to pool several deciduous teeth in order to acquire sufficient material.

The proposed milk teeth census is, of course, a long-range programme. If a continued general trend toward a rise in radioactivity in children's teeth were ascertained, it might well have important bearings on national and international policy. The results should be conveyed to the public without interpretations which might give rise to either complacency or fear, but rather in a spirit that would encourage sober, continued, active concern. It should be emphasized that the data would portray the situation as it existed about seven years previous to the study. In spite of this, the fact that these data would give a general estimate of the exposure of newborn children to radioactivity should be stressed.

Measures to keep the radioactivity of teeth and bone structure at low values, especially in young children, should—in accordance with the results of the study—be initiated with full public explanation, emphasizing the limitations of such measures. In connexion with the diet, the increasing use of soybean milk, especially in the Orient, would make it of interest to compare the radioactivity in milk teeth of children reared on soybean milk with that of children drinking cow's milk. The former might be less radioactive because the added calcium stems from rock which represents ancient deposits that have not been in contact with radioactive fall-out. However, the calcium present in the soybean itself may actually exceed that of dairy milk with respect to concentration of strontium-90. An appreciable group of children inhabiting the Pacific islands and Japan derive their calcium intake from fish-bones which might be relatively high in strontium-90, although the dilution factors of the ocean may tend to produce lower values.

It would be most effective if the International Milk Teeth Radiation Census could be carried out simultaneously, or nearly so, throughout the world. The United Nations might be the best agency to handle such a project. It would be particularly impressive if the Western world—which has contributed so greatly to the development of ingenious tools for the peaceful use of atomic energy—took the initiative by offering to make its equipment and technical advice available to any country interested in participation in this project. India, for example, would be uniquely equipped to give impetus to the study in the Orient, both as a direct participant and as a means for contact with China and other countries of the Far East which would have much to contribute.

---

* Present address: School of Biology, Johns Hopkins University.

In another continent, the Scandinavian countries, and notably Denmark, might be in a position to play a comparable part. Such a concrete demonstration of respect and reverence for life, regardless of creed, colour, or political system, might well contribute to a growing feeling of confidence among nations, and a special confidence in those nations which might elect to give initiative to or participate in a world-wide study of this kind.

It is a pleasure to express my gratitude to Dr. Warren Weaver, vice-president of the Rockefeller Foundation, for his kind interest and encouragement and for his valuable advice during the formulation of this article.

THE INTERNATIONAL SCIENCE HALL AT THE BRUSSELS EXHIBITION

THE exhibition in the International Science Hall at the Brussels Universal and International Exhibition is designed to show the aims, methods, and results of pure scientific research in the fundamental sciences, with a special emphasis on developments since the last World Exhibition was held in New York in 1939. The exhibits are restricted to four main topics of research—the atom, the crystal, the molecule and the living cell—and are arranged in the main body of the hall in four overlapping sections, one for each of these subjects. The growth of science from the earliest times to the present day is illustrated in the entrance hall.

The scope of the exhibition is perhaps best indicated briefly by a list of the headings under which the exhibits are described in the catalogue. In "The Atom" section these are: atoms and nuclei, isotopes, radioactivity, neutrons and fission, nuclear reactors, accelerating machines, elementary particles, cosmic rays, cloud and bubble chambers and nuclear plates, solar energy and thermonuclear reactions. In "The Crystal" section they are: the crystal lattice and lattice defects, the determination of crystal structures, crystal growth, dislocations and diffusion, phase changes, mechanical properties, electrical and magnetic properties, optical properties and crystal surfaces. In "The Molecule" section the main headings are: chemical bonds, molecular energy states, structural properties, techniques of separation (including thermodiffusion and chromatography), catalysis and kinetics, surface phenomena, colloids, radiochemistry, general chemistry and macromolecules. Finally, in "The Living Cell" section, the exhibits are concerned with the chemical constituents of cells, genetics, radiobiology, viruses, bacteriophage and bacteria, protozoa and fungi, photosynthesis and vegetable cells, animal cells and embryology.

The idea of staging an international exhibition of pure science as part of the Brussels Exhibition was due entirely to the Belgians, who have also provided the hall, the essential organization and a large number of the exhibits. Fourteen other countries, Austria, Czechoslovakia, the Federal German Republic, France, Holland, Israel, Italy, Portugal, Spain, Switzerland, the United Kingdom, the U.S.A., the U.S.S.R. and Yugoslavia, have also contributed to it. The overall plans were made by a committee of scientists from all the participating countries under the chairmanship of Prof. Robert van Cauwenberghe, and the exhibits were selected and co-ordinated by four sub-committees with the Belgian scientists, Profs. M. de Hemptinne, W. Dekeyser, G. Smets and P. Bordet, as chairmen respectively for the Atom, Crystal, Molecule and Living Cell sections. The individual exhibits, of which there are about five hundred, have been devised by leading scientists in the contributing countries, generally with the assistance of professional designers.

One of the principal objects of the organizers is to show that pure scientific research is a truly international activity. A great deal has been done, therefore, to avoid attracting attention to the differing nationalities of the contributors and to emphasize the aims and methods they have in common. The exhibits are arranged strictly according to their scientific content without regard for their country of origin; they are more or less uniform in design and the names and countries of the scientists responsible for them are displayed for the most part in an unobtrusive manner. Naturally enough, the exhibits do not all conform exactly to the recommended standard pattern, but there is certainly enough general uniformity of design for the organizers' main aim to be realized, and the few exhibits that are markedly different add a necessary touch of variety to the whole.

It is hoped that all sections of the public will visit and profit by this exhibition, and exhibits have therefore been provided both for laymen and for specialists. In addition, the Belgians have made a special introductory film in which most of the concepts necessary for an understanding of the exhibits are introduced in simple terms for the benefit of visiting non-scientists. This film is shown at regular intervals during the day in a special cinema inside the hall, every seat of which is equipped with ear-phones on which the film commentary can be heard in any one of the five languages, French, Flemish, English, German and Spanish. There are two smaller cinemas in which programmes of the best scientific films made by all the contributing countries are shown.

The exhibits in the hall are of three main types. Those of the first kind are intended to supplement the film in introducing the fundamental ideas and principal experimental techniques of modern research to visitors with little or no scientific training. These exhibits include, for example, atomic models, explanatory models of instruments such as the cyclotron, a demonstration of diffraction phenomena and their use in crystal structure analysis, an explanation of chemical bonding and an account of the Mendelian laws of heredity vividly illustrated in a collection of birds and animals. The exhibits of the second type are historical and show by means of original documents and models and replicas of famous apparatus the development of important experimental techniques and the performance and significance of crucial experiments. Among them may be noted the account of Becquerel's discovery of radioactivity in uranium, a model of the laboratory in Cambridge where Cockcroft and Walton first split the atom without the use of natural radioactivity, and a replica of the remarkably simple apparatus with which Hahn and Strassmann first recognized nuclear fission.

The remaining exhibits, those of the third type, which far outnumber the rest, are concerned with the methods and results of the latest research. They include a great deal of working apparatus—in the Atom section, for example, there are two working nuclear reactors—and many of them are concerned with quite advanced ideas. The general level of difficulty in fact approaches that of the exhibits at a Royal Society conversazione. It is scarcely fair to single out any of these exhibits for special attention, but some account of the Russian exhibits may interest the many people who are unlikely ever to visit the U.S.S.R., and it will also serve to indicate the standard attained by the exhibits in general. They are characterized by large frameworks standing on illuminated bases of metal and glass and carrying diagrams and models in fluorescent paint and neon lights which illustrate the subject of the exhibit. These centre-pieces are designed to attract attention to the exhibits, the serious contents of which generally consist of the latest apparatus, usually in working order and operated by a resident staff of scientists and technicians, and accounts of the results obtained by its use. Thus in the Crystal section the Russian exhibit on crystal structure determination by means of X-ray and electron diffraction consists of an array of crystal structure models mounted on a characteristic centre-piece, alongside an elegant apparatus for electron diffraction studies of single crystals from the Crystallographic Institute of the Academy of Sciences in Moscow. In the Molecule section the exhibit on chain reactions by Prof. N. N. Semenov, who shared with Sir Cyril Hinshelwood the 1956 Nobel Prize for Chemistry, has for its central feature an elaborate panel in which the course of various reactions is illustrated by means of automatically controlled lights. This is surrounded by apparatus used in the study of such reactions, including a mass-spectrograph for the study of free radicals, a high-speed camera for the study of explosions and an apparatus for the study of reactions under high pressures.

The British contribution of more than fifty exhibits in all parts of the hall was organized by Sir Lawrence Bragg, at the Royal Institution, with the special co-operation of Prof. C. F. Powell and the United Kingdom Atomic Energy Authority in the Atom section, Prof. E. R. H. Jones in the Molecule section, and Prof. Alex. Haddow in the Living Cell section. The individual exhibits were arranged by scientists throughout the country with the help of many university and government laboratories and industrial organizations. Most of them were designed in general accordance with the standards recommended by Gunther Hoffstead.

The British exhibits in the Atom section include models of the Cockcroft–Walton laboratory, the 7-GeV. proton accelerator now being built at Harwell and the Harwell tandem generator. They also include a modern mass-spectrometer shown in comparison with a replica of the 1937 Aston mass-spectrograph from the Cavendish Laboratory, and an exhibit illustrating the discovery of mesons in cosmic rays. In the Crystal section they include accounts of the structures of collagen, deoxyribonucleic acid and vitamin B_{12}, determined by the methods of X-ray crystallography, together with a description of the tertiary structure of the protein myoglobin, also determined very recently by these methods. Also included are exhibits on neutron diffraction investigations, the growth of crystals and the nature of crystal surfaces and dislocations as they are observed directly by electron microscopy. In the Molecule section they illustrate polar molecules, electron magnetic resonance, chromatography, insulin, vitamin B_{12} again, reaction kinetics, conformational analysis and radiochemistry. The British exhibits in the Living Cell section include accounts of proteins, cell division, 'lamp brush' chromosomes, the human chromosome number, the function of deoxyribonucleic acid, radiobiology, the structure of viruses, the malaria parasite, the mechanism of muscle contraction, the fine structure of *Amoeba proteus* and the effects of vitamin A on cells grown in tissue culture. The film programmes shown daily in the small cinemas include a high proportion of British films on loan for the duration of the exhibition from a number of laboratories, film libraries and film makers.

The International Science Hall has now been open to the public rather more than two months and a large number of people have visited it. Many of them agree that although it is more than usually successful in presenting science at a popular level, it is most successful as a science exhibition for scientists. Visitors who have had no scientific training are often overawed by the scope and complexity of the exhibits, despite the many ingenious efforts that have been made to explain them. The people likely to profit most from visiting the Science Hall are undergraduate scientists and specialists, who will find there a review of the latest research in physics, chemistry and biology provided by leading authorities in each subject, and also a striking demonstration that science is best learned as a whole rather than divided into separate subjects that become increasingly less self-contained as knowledge advances. The exhibition closes on October 19.

D. C. PHILLIPS

ANTARCTIC RESEARCH

THE idea of holding an informal symposium on Antarctic research in New Zealand during February 1958, following the relief of Antarctic stations, was first discussed by the members of the United States and New Zealand National Committees for the International Geophysical Year. Conceived as a meeting between American and New Zealand field scientists, its scope was broadened at the 1957 Paris conference to include all nations with a working interest in the Antarctic. The confluence of several expeditions at Wellington was rather demanding in view of the exigencies of Antarctic operations but, through the goodwill of all and some sacrifice on the part of many, about seventy scientists from

Australia, France, Great Britain, New Zealand, South Africa, the United States and the U.S.S.R. were able to attend the meetings held in Wellington during February 18–22.

The participants were welcomed to New Zealand by the Prime Minister (the Right Hon. Walter Nash, P.C.) at a morning reception. Mr. Nash expressed the hope that future Antarctic research would take place "in the spirit of the International Geophysical Year". Business meetings of two types were arranged: the general meeting, at which informal papers would be presented; and the discussion meeting, mainly confined to the round-table conference of specialists. A considerable number of visiting and New Zealand scientists attended the latter meetings to listen to the discussions. Each meeting was presided over by a worker in the subject, and because of the informal nature of the symposium no attempt will be made to present the full proceedings.

The first meeting, devoted to "Special Investigations in Glaciology", had as its chairman Dr. J. Zumberge (United States). So much material was available on this subject that a whole day was devoted to it. Dr. T. Pewe (United States) outlined his summer's work on the glaciological history of McMurdo Sound, mourning the fact that the terminal moraines, from which a good deal of the history can be read, lie on the sea-bottom. Apart from two late Pleistocene glacial advances, there is evidence of a much older and more extensive advance of the Antarctic ice cap into McMurdo Sound, which covered all the valleys in the area and filled the Sound itself with glacier ice. Questions concerning the synchronism of Antarctic glacial cycles with other regions will probably best be answered by carbon dating of the samples collected from the deltaic beds in the ponds of the Ferrar and Koettlitz Glaciers. Periglacial processes on Antarctic rocks between 50° E. and 170° E. were described by Prof. K. K. Maarkov (U.S.S.R.). The physical and chemical weathering processes are similar to areas such as the cold, highland deserts of Asia as well as northern and western Greenland, the dominant factors being long duration of solar radiation, low humidity and low temperatures. Solifluction is observed but is feeble. The techniques of obtaining ice cores, developed in Greenland, were applied to a borehole at Byrd Station, which reached a depth of 1,013 ft. The Failing 1500 rig was operated by three men and 98 per cent of core was recovered, a remarkable achievement. The bottom layer is of the order of 700 years old, there being an average annual accumulation of 20 cm. water equivalent. E. W. Marshall (United States), after describing these efforts, gave a detailed list of temperatures and densities. More primitive methods were used by R. Cameron (United States) at an inland base 50 miles from Wilkes Station, where a pit 2 m. square was dug to a depth of 35 m., an auger hole being drilled a further 27 m. Stratigraphy, density and sastrugi patterns were investigated. At a depth of 33 m. a tunnel 2 m. in diameter and 6 m. long was excavated to study deformation. The average annual accumulation was 15 cm. water equivalent. A comprehensive account of the detailed Soviet studies on the movement, mass economy, heat balance, temperature regime, form and thickness, snow cover and alimentation of the Antarctic ice sheet was given by Prof. P. A. Shoumsky (U.S.S.R.). The east Antarctic ice sheet has a complex irregular form conditioned by sub-glacial relief; on the whole, it probably approximates to a flattened ellipse with irregularities introduced by the topography of the bedrock.

Deformation of the Ross Ice Shelf produced by the presence of Roosevelt Island was the subject of a special study by a team led by Dr. J. Zumberge. An extensive grid was surveyed during the past summer, and by repeating the survey in the summer of 1958–59 it is hoped to measure the rate of strain in various directions. Use was also made of dial strain gauges to measure the change in width of crevasses. Ice structures resulting from compression, tension and shear are all present in the area. The Ross Ice Shelf is between 230 and 290 m. thick around Little America, 300 m. thick off Minna Bluff and 420 m. thick near the Beardmore Glacier, being still afloat in the latter position, according to H. Bennett (United States), a member of the Ross Ice Shelf traverse party which covered 1,440 miles over the Shelf during the past summer. Seismic shots every 30 miles were supplemented by gravity and magnetic observations and glaciological pit work. The thickness of the ice and the depth of the bottom of the Ross Sea were obtained by using the measured travel-time for reflexion from the sea bottom and assumed velocities for ice and water.

B. Imbert (France) was chairman at the second meeting, on "The Topography of the Sub-Glacial Continent". At this meeting the provisional results of all traverses except that of the United States party to the Weddell Sea were presented and techniques discussed, even though at the time of the symposium some traverses were not quite completed (Fig. 1). Considerable geographical discoveries were made by the Byrd Station traverse party and during the support and reconnaissance flights. From the Ross Ice Shelf–Rockefeller Plateau boundary to the end of leg 1 (76° 30′ S., 113° W.) the ice–rock interface is rough, the thickness of the ice varying between 600 and 2,700 m.; all but a few peaks of the rock floor are

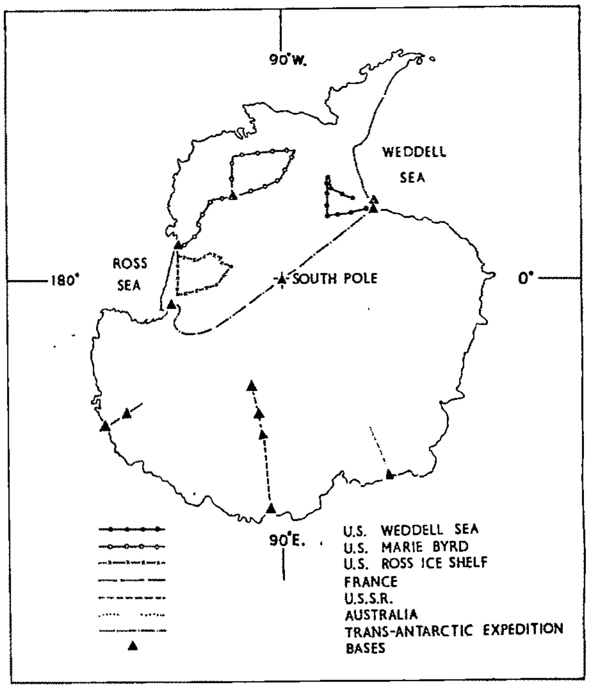

Fig. 1. Antarctica, showing major scientific traverse routes (1957–58)

at present below sea-level, the major portion far enough below to be under water if the ice were removed and the land allowed to rise into isostatic balance. Leg 2 shows quite a different picture, with a smooth bottom, great thickness of ice (from 2,300 to more than 3,500 m.), and broad gravity anomalies. Near the middle of the leg the rock floor reaches a depth of 2,000 m. below sea-level at a point where the elevation of the surface is a little more than 1,500 m. Leg 3, south-west from the Sentinels (77° 30′ S., 89° W.) was in a still different type of area—the rock floor being very rough and mostly above sea-level, breaking the ice surface in several places to form nunataks. This evidence indicates, subject to further examination of rock samples, that the Sentinels structure extends south-west at least as far as 80° 30′ S., 98° W.

The results of the Soviet, Australian and French radial profiles in East Antarctica showed some similarity, that is, complexity of land topography, mainly above sea-level except near the coast, but with great thicknesses of ice as high altitudes were reached. Dr. F. Jacka (Australia) noted the successful use by the Australians of a powered auger which enabled them to lay charges at depths of 30 m. There was agreement among all speakers that a small charge detonated at as great a depth as possible contributed greatly to good seismic records. G. Pratt, seismologist with the Trans-Antarctic Expedition, forwarded his preliminary results from Southice to Midway depot (81° 30′ S., 146° 09′ E.). On the Weddell Sea side of the South Pole the land surface is typically 1,000–3,000 ft. above sea-level and probably never below it ; several ridges rise to a maximum of 7,000 ft. Twenty-five miles either side of the Pole the ice is very much thinner than at the Pole itself, and on the Ross Sea side remains thin, occasional crevassed areas being apparently on top of peaks covered by only 1,000 ft. of ice. The seismic results are generally confirmed by gravimetric data, but inaccuracies of the free air corrections weakens this support. American traverse parties endeavoured to minimize the effect of changing atmospheric pressures on elevations by leap-frogging. Considerable interest was shown in the experiences of the airborne seismic and glaciological unit under Dr. J. C. Cook (United States) operating from McMurdo Sound. Seismic soundings, gravity readings and glaciological studies were made at three stations on the plateau west of the Royal Society Range. At one of these stations the aircraft remained on the ground, while at the other stations the aircraft returned to base during observations. The seismic soundings were not very successful. Gravity deficiencies of more than 100 mgal. below McMurdo pendulum station were obtained, assuming ice to sea-level. A negative anomaly of similar magnitude is reported from the South Pole.

Dr. H. van Loon (South Africa) took the chair at the session on "Meteorology", which was opened by R. Taylor (United States) with an account of the work of Weather Central and the complex communication and reporting network which supplies information to Little America. Commander J. Mirabito (United States) recalled the great difficulties of operational forecasting in the Antarctic during 'Deepfreeze' I and II before the reporting network got into stride, when long-range flights were made on forecasts using data from McMurdo Sound supported by a few scattered ships. Air operations, however, have never been hampered by strong winds, and Commander Mirabito could only recall one incident involving aircraft icing during polar flights. I. Kerr (New Zealand) pointed out that with the present reporting network, Antarctic weather data are available to mid-latitude forecasters, but so far they have made little improvement in the effectiveness of New Zealand forecasting. Any improvement would be through a better knowledge of general atmospheric circulation and processes resulting from Antarctic studies. In common with other meteorologists in the southern hemisphere, he emphasized the large oceanic gaps in reporting centres, which only weather ships could fill. Forecasting of gales at a station where synoptic data were not available was discussed by Dr. J. Shear (United States). Changes in pressure were of little use, and though cloud sequences were classical and informative, Shear found that the most effective tool was a 'time-hodograph' of the wind vector at the 500-mb. level.

Soviet aerologists led by Dr. O. Krichek considered that the configuration of the Antarctic continent and particularly its northward extensions was responsible for six regions of stable high-pressure tongues. Reinforcement of these tongues blocks cyclones over the adjoining seas, and zones of stationary cyclones between these ridges occur in the Weddell Sea, off eastern Queen Maud Land, Mackenzie Sea, off Wilkes and George V Land, and in the Ross Sea. Ridges of the Antarctic anticyclones may connect with subtropical anticyclones, inhibiting zonal circulation, which is by no means exclusively typical in the southern hemisphere. Aerial reconnaissance for ice over the Davis Sea confirms that the cyclonic zones have a substantial effect on the position of the ice belt. At Mirny during the winter, inversions of up to 35° C. were recorded and often persisted, though down-slope winds reached a velocity of 40 m./sec.

Prof. H. Hoinkes (United States), who was chairman of the session on "Radiation", discussed the heat balance equation at Little America. He carefully measured or assessed the various factors: radiation balance, turbulent exchange, latent heat change, precipitation exchange and conduction from below. Latent heat, precipitation exchanges and conduction from below are not significant. Winds and temperatures measured at several levels up to a height of 17 m. show that turbulent exchanges are rarely of much importance at Little America. Thus, radiation balance is the only important term in the equation and this was studied with a Link–Fuessner solarimeter, Schultze net radiometer and an Ångström pyrgeometer. The lowest outgoing radiation recorded was 0·08 langley/min., but only occasionally was 0·06 langley/min. exceeded. Inversion in the presence of clear skies would decrease this to 0·02 langley/min. Summer albedos were remarkably high. At the South Pole the mean of 100 readings was 0·89 (range, 0·845–0·943) ; at Byrd Station 0·88, and at Little America 0·90 after fresh snow.

A unique and important part of the Soviet radiation programme, described by Dr. V. I. Shliakhov, was the measurement of the short-wave radiation balance at various altitudes. Special flights were made for this purpose. The great transparency of the Antarctic atmosphere undoubtedly accounts for the very low linear gradient of 0·0004 langley/min. per 100 m. up to 4,500 m. The figure for medium latitudes in Europe is 0·03–0·04 langley/min. per 100 m. The instrumental diversity in measurements of radiation made at Antarctic stations was very apparent in discussion. Shliakhov used a Yanishevsky balance meter and attempted to protect it from wind and snow damage by shielding it with a polyethylene cover 20 μ thick. A minor parlour game was played of deriving the minimum possible surface temperature in Antarctic regions. Shliakhov gave − 80° C. ± 2° C., while Taylor preferred − 78° C. The lowest surface temperature recorded at the South Pole station during 1957 was − 74° C.

The chair for the session on "Oceanography" was taken by R. M. Cassie (New Zealand). The presence of the Soviet research ship *Ob* in Wellington during the symposium ensured a strong representation of Russian marine scientists. An account of the first two Antarctic cruises of *Ob* (1956 and 1957) was given by Prof. V. Kort. During these two cruises 329 oceanographic and 225 geological stations were occupied, mainly in the Indian sector of Antarctica. About 150 cores 2·0–5·5 m. long have been taken by a gravitator tube, and five cores of 16 m. have been taken by a piston corer. The present cruise is charged with similar investigations in the Pacific sector of Antarctic waters. From continuous echo soundings and cores, Dr. A. V. Jivago (U.S.S.R.) was able to discuss the types of bottom relief in the southern Indian Ocean and east Antarctic seas. Extremely complicated volcanic relief covers approximately two-thirds of the area explored. Besides the known volcanic chains extending from the Atlantic Ocean across the Crose plateau to the Kerguelen–Gauss range, big sub-surface volcanoes have been discovered to the west of Heard Island and north-west of the Prince Edward Islands. Their relative heights reach 3,000 m. Vast areas consist of lava plains with stepping, hilly and block surfaces. The Antarctic Shelf, which represents the most complicated type of relief, was investigated in more detail. Its boundary is considerably deeper than other continents (500 m. or more), the surface is often rough and in some places devoid of covering sediment. Several morphological sub-types have been distinguished within the Shelf limits.

According to Dr. A. P. Andriashev (U.S.S.R.), who described the ichthyological investigations of *Ob*, 1,100 specimens representing 75 species and 16 families have been caught. In the shallow water of the eastern Antarctic continent, trematoms and *Gymnodraco acuticeps* are the most abundant species, and some of these, especially *T. bernacchi*, may have some fishing importance to wintering-over parties. New types of chænichthyid and harpagiferid fishes were found among fishes caught by trawls at depths between 100 and 3,000 m. Eight more species of the white-blooded chænichthyidae were added to the five already known. Qualitative investigations of the bottom and plankton invertebrates have shown the extremely low productivity of food forms (for fishes) of the bottom fauna, in comparison with the rich development of the pelagic crustaceans, substantiating Nybelin's hypothesis concerning the cause of partial transition of many bottom notothenioid fishes to pelagic feeding habits. The factors governing the character of bottom fauna of the shelf are the great depth of the boundary, complicated relief, extremely poor sorting of bottom sediments, and strong bottom currents which carry the subsiding detritus away to the ocean. Consequently, an extremely rich and varied fauna of sponges, cœlenterates, bryozoans, brachiopods, ascidians and an impoverished fauna of crustaceans and molluscs are characteristic of the Shelf. One of the main differences between the Shelf faunas of Antarctica and that of other areas is that the polymixtous nature of the former makes it very difficult to ascertain the leading species.

Dr. R. W. Burling (New Zealand) exhibited a vertical section of isotherms south of New Zealand, in which tongues of cold water are present in positions suggesting the existence of a large horizontal eddy. Such eddies would have a great influence on mixing between various water masses in their predominantly eastward flow. The theoretical model of the Antarctic circumpolar current propounded by Hidaka and Tsuchiya, in fact, requires an occurrence of such eddies.

Dr. T. Hatherton (New Zealand) was chairman of the session on "Seismology". Epicentres within the Antarctic area were reported only by Scott Base (including tremors from Erebus) and Halley Bay, although stations along the coast of East Antarctica report a plenitude of seisms from the Indian Antarctic swell. Both d'Urville and particularly Scott Base reported remarkable changes in microseismic activity, very low in winter, very high in summer, presumably related to the effect of pack ice on the generation or transmission of microseismic energy. The successful operation of seismographs on floating ice (Halley Bay) and inland *névé* (South Pole and Byrd) was of considerable interest.

The chair for the meeting devoted to "Biology" was taken by Dr. R. A. Falla (New Zealand). Observations made on the Byrd traverse were summarized by Dr. D. Hale (United States). Eleven snow petrels and twelve skua gulls were sighted at distances more than 300 miles from the coast. A penguin track was discovered at 77½° S., 99° W. at an altitude of 1,260 m. The track was followed for more than a mile and traces of urine and fæces obtained. More than sixty specimens of lichens were collected; the entire collection with possibly two exceptions seems to be composed of species previously undescribed. *Umbelicaria* is noticeably absent and there is no *Usnea* sp., which is present all along the coast of Antarctica. *Lecedia* sp. and *Buellia* sp. predominate, as might be expected, and *Alectoria* sp. seems fairly widespread. In the Sentinel Mountains area individual nunataks, though fairly close in location, may have rather different floras. Flora affinities seem to be with the lichens of the west coast rather than with those of the Edsel Ford Mountains.

Dr. K. A. Brodsky (U.S.S.R.) has examined the mass development of phytoplankton in the cold waters near the continent, and along sections on the 90° E. and 78° E. meridians, with the northern boundary near 63° S. Zooplankton was poor in waters rich with phytoplankton, but increased to the north. The biomass in the northern regions did not exceed 0·75 gm./m.^{3}, whereas in the phytoplankton zone there was not less than 1 gm./m.^{3}, sometimes reaching more than 7 gm./m.^{3}. In Antarctic waters the cold intermediate layer is not impoverished, but is somewhat richer in plankton than the superficial one. Brodsky considers that the term 'Sub-Antarctic', like 'Sub-Arctic', should be discarded for biogeographical purposes. He prefers a subdivision into 'Antarctic' (northern boundary between 60° S. and 52° S. for different areas), 'Notal' (northern boundary between 50° S. and 40° S.) and 'Tropical'. Brodsky proposes using the composition and distribution of the Celanoid to compare the biogeographical regions of both hemispheres. Data on bird-banding, seal-branding and other studies were exchanged, and

Pewe reported the discovery of 81 carcasses of crabeater seals at altitudes of 1,000–2,000 ft. in the foothills of the Prince Albert Mountains.

Dr. F. Jacka (Australia) occupied the chair at the session on "Aurora". Interest centred mainly on radio echoes and the problem of relating them to visually observed auroras. At Invercargill, all-sky camera and very high-frequency radio-echo equipment have been run continuously. M. Gadsden's (New Zealand) analysis of six months results showed that the probability of aurora being present at the same time as radio echoes increases with increase in local K-index, suggesting that there is no intimate connexion between visual aurora and radio echoes. Radio echoes show a broad maximum in occurrence at local midnight (35 per cent) and a minimum shortly before local noon (3 per cent), whereas no significant diurnal variation has been detected in the occurrence of visual auroras. The echoing region heights average 110 km. and, with the radar looking south, radial velocities are generally inward (that is, northward) before local midnight and outward (southward) after, with an average north/south radial velocity of 400 m./sec. K. Bullough's (France) measurements at d'Urville (geomagnetic latitude 75·5° S.) showed that diurnal distribution of echoes displays a very sharp peak in the evening in winter with more even occurrence throughout the day in summer. The echoes occur almost entirely to the north during the winter months, with a marked increase in activity to the south in summer. Skip echoes are believed to have been observed on three occasions. Analysis of the d'Urville results is not yet sufficiently advanced to permit correlation with visual activity. All stations reported little success with spectrographs. Many observers commented upon poor design and engineering features which restricted the operation of their instruments. Little discussion was possible on visual auroral observations at Antarctic stations as the results have not yet been reduced.

The closing session was devoted to "Future Research in the Antarctic", with Dr. G. de Q. Robin (Great Britain) in the chair. Seven speakers discussed future work in their respective fields. Dr. F. Jacka, dealing with the physics of the upper atmosphere, requested more studies of 'whistlers' and the 'dawn chorus', which have hitherto been almost entirely neglected. He also suggested a better geographical distribution of cosmic ray stations, which are at present concentrated around the coast of the African–Australian quadrants. Spectrographic studies of the aurora have been less successful than expected. Simpler instruments with more limited objectives might be preferable for future work. B. Imbert, speaking on ice cover and glacial relief, reviewed the achievements of the past year in seismic sounding, and came to the conclusion that tractor trains with close air support, using mechanized drilling techniques to place a small charge as deep as possible below the surface, form the most desirable unit. The high plateau of east Antarctica offers the severest challenge. There was some discussion on the use of radio waves for soundings of the depth of ice, but in the absence of confirmed experiments using these techniques, normal seismic methods must continue to be used. The use of the triangular traverse was urged, as being more informative and easier to support. Prof. Shoumsky, dealing with general glaciological problems, outlined possible future Russian traverses, but urged that attention be paid to general ice regime, heat- and mass-balance as well as to form and dimensions. The morphology of the huge ice streams of the continent is an especially desirable study, but one of considerable difficulty because of the broken and crevassed nature of the boundaries. With regard to meteorology, R. Taylor considered that it is now possible to obtain a reasonable representation of the mean circulation over the Antarctic, but a comprehensive picture of southern hemisphere circulation is impossible in the foreseeable future, because of the lack of information over the southern oceans. He endorsed the use of weather ships, as did many other speakers at the symposium. As a by-product of Antarctic work, he predicted considerable improvement in many instruments. Meteorological flights have not been used as often or extensively as they should. Prof. V. G. Kort summarized comprehensively the needs of oceanographic research over the next ten years. In particular, he pleaded for much more concentrated work in zones of convergence and divergence, and in coastal waters an extension of hydrological work at coastal stations, where remarkably few oceanographic studies are done, and comprehensive studies of the pack ice by monthly flights from coastal bases. Actinometric studies have been successfully carried out this season on *Ob* and offer considerable scope in the future.

Dr. R. A. Falla considered that biological studies in the Antarctic had benefited during the International Geophysical Year although they were not planned explicitly, except in the case of the larger vertebrates, where banding and branding studies had been successfully carried out. Amateur observers could do valuable preliminary studies in biological fields, which could be examined to see where professional studies were required. He cited as an outstanding example the collection of lichens from the Marie Byrd Land mountains by the Byrd traverse party. Intensification of taxonomic, ecological and physiological studies was required. Biological research suffers from inadequate national and international organization, and this must be remedied before Antarctic biological research can achieve the same effectiveness as that in the physical sciences. Falla ended with a plea for the greater participation by mature scientists in expeditions, thus emphasizing a weakness in most British Antarctic teams, which rely unduly on the efforts of young graduates.

Dr. T. Hatherton, speaking on the future of crustal geophysics, emphasized the need for precise levelling to the main inland bases. Antarctic seismic activity appears to be present only in the areas of the Ross and Weddell Seas, and determinations of epicentres require at least two stations. He suggested that such dual stations (less than 100 km. apart) might be useful also for gradient and movement investigations in the upper atmosphere, though Jacka preferred dispersion of the stations in ionosphere studies. Seismic and magnetometer work at sea in the areas of most structural interest were recommended. Geology needs no specific recommendations but should be carried out wherever exposures are available. Dr. Robin closed the meeting by pointing out that the best contribution that scientists attending the symposium could make to future research was to work up their results as soon as possible, before new interests and opportunities arise to distract them from completing their Antarctic work by its final publication.

T. Hatherton

NOMENCLATURE OF ROCK UNITS IN THE ROSS SEA REGION, ANTARCTICA

By Dr. H. J. HARRINGTON
New Zealand Geological Survey

A MEETING of ten British Commonwealth geologists who had worked in Antarctica with the Trans-Antarctic Expedition, the New Zealand Ross Sea Expedition, the New Zealand Geological Survey Expedition and the Falkland Islands Dependencies Survey, was held in Wellington in March to exchange information gathered in recent seasons. It became clear that communication of results is hampered by an almost complete lack of a formal nomenclature for rock units of the Ross Sea–Weddell Sea region, the rocks being described, except in the case of the Beacon Sandstone, as 'the Dolerites' or 'the Schists and Marbles' and so on. A nomenclature for the major regional units was devised at the meeting for use in forthcoming publications and maps and, as there are no international arrangements for this matter, it is set out below with explanatory notes. It should help to prevent the confusion that could arise if different nomenclatures were proposed by geologists of expeditions now scattered in several homelands. In devising it, the meeting had as part of its background a knowledge of some of the recent work by United States and Soviet geologists described at an earlier meeting held in Wellington in February.

Quaternary	Moraines, beaches, etc.
Upper Tertiary and Quaternary	McMurdo Volcanics
? Jurassic or Cretaceous	Ferrar Dolerites
Palæozoic and Mesozoic	Beacon System
Lower Palæozoic or Precambrian	Admiralty Intrusives
Lower Palæozoic or Precambrian	Ross System

McMurdo Volcanics (*Group*). This term is proposed for the volcanic rocks of Quaternary and possibly Upper Tertiary age in the Ross Archipelago and other islands in the Ross Sea, the Balleny Islands and Scott Island, and parts of the coast of Victoria Land. The unnamed volcanic rocks of Marie Byrd Land are tentatively excluded. The name 'Ross Volcanics' is not used, to avoid confusion with the volcanic rocks of James Ross Island (Graham Land).

Ferrar Dolerites (*Group*). Dolerite sills and dykes occurring abundantly in the Beacon Sandstone in the Ferrar Glacier district and other parts of Victoria Land, and also in the Beacon System in Adelie Land, and elsewhere, are called the Ferrar Dolerites. Several geologists at the meeting considered that the dolerites of Adelie Land and elsewhere should be distinguished within the group by regional formation names from the type Ferrar Dolerites (Formation) of Victoria Land.

Beacon System. The Beacon Sandstone was named by Ferrar from its occurrence at Beacon Heights in Victoria Land. Similar sandstone and associated sediments occur widely in far distant regions in Antarctica and have either been called Beacon Sandstone or compared and correlated with it. It was the opinion of the meeting that all occurrences could be classified together as Beacon System, that the type rocks in Victoria Land could be called Beacon Sandstone (Group), and that local group names might be appropriate at present in other regions.

Admiralty Intrusives (*System*). The system consists of pre-Beacon intrusives, predominantly granite and granodiorite, in the Ross System. The type rock is the Tucker Granodiorite (new name) of the Admiralty Mountains in northern Victoria Land. The granitic and granodioritic rocks of the McMurdo Sound region are included, as well as, tentatively, those of Marie Byrd Land.

Ross System. The pre-Beacon sediments and metamorphosed sediments so far described from the Ross Sea region are unnamed marbles, schists and associated rocks occurring in Victoria Land from Terra Nova Bay southwards through the Royal Society Range, the 'slate-greywacke formation of Robertson Bay', and unnamed thick 'greywacke'-type sequences of sandstone and shale in Marie Byrd Land. In addition, occurrences of limestone containing *Archaeocyathinae* are known in the Beardmore Glacier district, and seem to be extensive in the Weddell Sea region.

Recent field work has shown that the Admiralty Mountains of northern Victoria Land consist mainly of an assemblage of quartzose greywacke and argillite, meta-greywacke and meta-argillite, schist and some metamorphosed limestone which is being called Moubray Group (new name) and almost certainly includes the 'slate–greywacke formation of Robertson Bay'. Inspection of aerial photographs shows that this group extends south of the Admiralty Mountains towards Wood Bay and Terra Nova Bay. Farther south, rocks of closely similar lithology are associated with marble and schist in the McMurdo Sound region. It is suggested that all these rocks in Victoria Land may be called Ross System, the type beds being those of the Moubray Group. The rocks of the Ross System in Victoria Land give the impression of being the deposits in a major geosyncline in which the shelf sediments with carbonate rocks were deposited in the McMurdo Sound district and southwards, and the deeper-water sediments with few carbonate rocks were deposited in northern Victoria Land.

The sediments of the Moubray Group strike east-south-east into the Ross Sea and towards the very thick greywacke-type assemblages striking north and north-west of the Edsel Ford and Rockefeller Mountains in Marie Byrd Land. Several geologists at the Wellington meeting considered that this is reasonable evidence for tentatively including the Marie Byrd Land assemblages in the Ross System, though distinguishing them by the names Edsel Ford and Rockefeller Groups. If this is done, the only known pre-Beacon sedimentary rock of the lands surrounding the Ross Sea that is not included in the Ross System is the limestone of the Beardmore Glacier–Weddell Sea region that in at least one place contains *Archaeocyathinae*. It seems that its classification must await further work.

OBITUARY

Prof. J. K. Robertson

JOHN KELLOCK ROBERTSON, professor emeritus of physics in Queen's University, Kingston, Ontario, died suddenly in London on June 24.

Robertson came to Queen's as a lecturer in physics in 1909. He had entered the University of Toronto on a classics scholarship, but took his degree in mathematics and physics and spent two graduate years as demonstrator in physics. Except for two interludes of a year each, he remained at Queen's until his retirement from his posts as professor of physics and head of the Department in 1951. The session of 1912–13 he spent at the Cavendish Laboratory, Cambridge, and as a member of Emmanuel College. During 1933–34, he was a visiting professor at the Imperial College of Science and Technology, London.

As a physicist, Robertson's major interests were in the fields of optics and of X-rays and radiology. His text-book, "Introduction to Physical Optics" (1929), has run through successive editions, as did his "X-Rays and X-Ray Apparatus" (1924) and his "Radiology Physics" (1941).

He was an enthusiastic, patient and lucid teacher. His most distinctive courses of lectures were those which he gave to medical students. He was able to persuade his medical colleagues that the study of physics should be continued through two years, allowing more extensive work than was usual in North American medical schools. He was greatly pleased when the members of the last medical class which he taught made him an honorary life member of the class. His interest in medical physics continued after he gave up teaching, and he was an honorary member of the British Institute of Radiology and of the Association of Hospital Physicists.

He was elected Fellow of the Royal Society of Canada in 1926, was president of Section III in 1942–43 and president of the Society in 1944–45. After his retirement, when he spent at least part of each year in London, he represented the Royal Society of Canada and the National Research Council at a number of international gatherings.

Robertson was a literate physicist with a wide range of interests and friends. He had a talent for explaining physics to the layman ("Atomic Artillery and the Atom Bomb", 1945) and an active interest in literature.

He was a fourth-generation Canadian, born in 1885, in Perth, Ontario, which had begun as a Scots settlement some sixty years earlier. In 1932 he published a charming little book, "Sketches of Tayville", which had appeared earlier in the *Queen's Quarterly*, and which recalled his boyhood in a Scottish-Canadian town.

'J.K.' was a man of warm friendships and strong loyalties. He had a contagious enthusiasm for learning and scholarship. His gallantry turned what might have been a lonely retirement into a lively enjoyment of friendships and intellectual interests. He is gratefully remembered by former students and colleagues, by his brothers in the craft and by many friends on both sides of the Atlantic.

W. A. MACKINTOSH

NEWS and VIEWS

National Standards Laboratory, Sydney: Mr. N. A. Esserman

MR. N. A. ESSERMAN, chief of the Division of Metrology, has been appointed as the first director of the Commonwealth Scientific and Industrial Research Organization, National Standards Laboratory, Sydney. This appointment is one of the first consequences of the recommendations of a committee of the Advisory Council which reported last year on the future development of the National Standards Laboratory. Mr. Esserman was born and educated in Sydney, graduating in science with honours at the University of Sydney in 1916. Following a period during and after the First World War at the Arsenal Branch, London, he returned to Australia to join the Commonwealth Department of Defence, later becoming senior physicist, Munitions Supply Laboratories, at Maribyrnong in 1929, and assistant superintendent of laboratories in 1938. During this time, Mr. Esserman had accumulated a wide experience of metrology and general physical instrumentation and their application in the engineering industries. He was therefore well situated to assume the task of developing the newly created National Standards Laboratory when he was appointed senior officer-in-charge of the Metrology Section in 1939. Mr. Esserman took a major share in piloting this young establishment through the turbulent years of the Second World War. The virile engineering industries which have grown to maturity in Australia in the post-war years owe a great deal to the knowledge and experience which Mr. Esserman brought to his labours at the National Standards Laboratory. He also undertook, during the War, a number of other tasks associated with the general effort of munitions production in Australia. He was a member of the Optical Munitions Panel, the Australian Council for Aeronautics, and the Optical Advisory Panel of the Department of Post-War Reconstruction. Mr. Esserman is an active member of many scientific institutions in Australia, having held office as president of the Royal Society of Victoria, Fellow of the Australian National Research Council, chairman of the New South Wales Division of the Australian Branch of the Institute of Physics, trustee of the Sydney Museum of Applied Arts and Sciences, and member of the Technical Education Advisory Council and the International Committee of Weights and Measures. Mr. Esserman will retain his responsibilities as chief of the Division of Metrology.

Dr. G. H. Briggs

DR. G. H. BRIGGS, who is retiring as chief of the Division of Physics of the National Standards Laboratory, graduated in 1916 at the University of Sydney and was appointed lecturer and later assistant professor of physics at that University. His Ph.D. degree was gained in research in association with

Lord Rutherford at the Cavendish Laboratory. At this time and in subsequent research he made notable contributions in the accurate determination of the fundamental constants of nuclear physics, obtaining his D.Sc. degree in 1937. He joined the National Standards Laboratory of the Commonwealth Scientific and Industrial Research Organization at its inception in 1939, being appointed as officer-in-charge of the Physics Section, which became a Division in 1945. Under Dr. Briggs's guidance the Division has not only established a high reputation for research in the physical sciences but has also been of great assistance to manufacturing industry in Australia during its rapid growth during and after the Second World War. Dr. Briggs was scientific adviser to the Australian delegation to the United Nations Atomic Energy Commission during 1946–47; president of the Australian Branch of the Institute of Physics in 1950; and chairman of the Unesco Australian Committee for Natural Science during 1953–55.

Dr. R. G. Giovanelli

Dr. R. G. Giovanelli, who is to be appointed chief of the Division of Physics of the National Standards Laboratory in succession to Dr. Briggs, graduated in 1937 at the University of Sydney, was Research Fellow at the Commonwealth Solar Observatory, and after a short period on the staff of the Sydney Technical College, spent a year at the National Physical Laboratory, Teddington, before joining Dr. Briggs's staff at the National Standards Laboratory. He received his D.Sc. degree at the University of Sydney in 1950 for his studies on the physics of the solar atmosphere. Dr. Giovanelli is a Fellow of the Royal Astronomical Society, and was awarded the Edgeworth David Medal of the Royal Society of New South Wales in 1949. Dr. Giovanelli's main research interests have been in solar physics, the fine structure of the Sun's outer layers, solar activity and spectra, and the emission of radiation from high-temperature atmospheres.

Director of Fire Research: Mr. D. I. Lawson

Mr. D. I. Lawson, who has been appointed director of fire research of the Joint Fire Research Organization of the Department of Scientific and Industrial Research and the Fire Offices' Committee, is forty-seven. He was born in Sheffield and educated at Woodhouse Grammar School. After taking first-class honours in physics with mathematics at the University of Manchester and obtaining an M.Sc. degree for research in X-ray crystallography, he became a lecturer in physics and telecommunications at Woolwich Polytechnic in 1934. Five years later he became head of the Research Division at Pye, Ltd., of Cambridge. Mr. Lawson joined the Fire Research Station at Boreham Wood, Herts, in June 1948, since when he has specialized in problems of heat transfer and the ignition of materials. Since 1952 he has been assistant director to Mr. S. H. Clarke, whom he succeeded on August 1. Mr. Clarke has been appointed director of the Warren Spring Laboratory of the Department of Scientific and Industrial Research (see *Nature*, 182, 225; 1958), which is being built at Stevenage.

National Science Foundation: Dr. R. M. Robertson

Dr. Randal M. Robertson, who has been appointed to the staff of the National Science Foundation as assistant director for mathematical, physical and engineering sciences, was born in Tampa, Florida, and graduated in mathematics and natural philosophy at the University of Glasgow and received a Ph.D. in physics from the Massachusetts Institute of Technology. He taught briefly at both institutions before serving as a research assistant at Columbia University. During 1937–42 he was a research associate with the Norton Company in Worcester, Massachusetts. During 1942–46 he was on the staff of the Radiation Laboratory at the Massachusetts Institute of Technology. In 1946 he went to Washington as head of the Mechanics and Materials Branch of the Office of Naval Research. In 1948 he became director of the Physical Sciences Division, and has been director of the Research Group since 1952. He has conducted research on arc-cathode phenomena; nuclear magnetic moments; physics of solid materials, especially abrasives and refractories; and microwave linear-array scanning antennæ.

British Scientific Attaché in Moscow

In reply to further questions in the House of Commons on July 1 regarding the grading of the post of British Scientific Attaché in Moscow as principal scientific officer instead of deputy chief scientific officer as in Washington, Mr. H. Nicholls, Parliamentary Secretary to the Minister of Works, as representing the Lord President of the Council, repeated what was said on June 17 and 24, namely, that if a suitable candidate could not be found, the grading would be reconsidered. There was no question of wanting to have a higher grade officer in the United States than in Moscow. The immense interchange of knowledge with the United States has justified the team of men with the higher grade there, and when there is any likelihood of getting the same co-operation in Moscow the matter will be reconsidered. Appointment of a higher grade scientist was not excluded; but in opening the new service, the manner of approach rather than scientific qualifications was the more important.

Plutonium from Civil Nuclear Power Stations

An adjournment debate in the House of Commons on July 11 on a motion of Mr. A. Palmer's on the use of nuclear power stations constructed under the civil programme of the Central Electricity Generating Board for the production of military plutonium elicited a sharp reply from the Parliamentary Secretary to the Ministry of Power. Sir Ian Horobin repeated the specific assurance that all the capital costs of the civil stations will be met and it is the firm intention of the Government, the Atomic Energy Authority and the Central Electricity Authority, in fixing the prices at which the fuel rods will be bought back, to take account of any additional operating costs incurred in neutralizing them. Sir Ian said that a vital part of the economic calculations of the competitive position of nuclear power stations depends upon the number of megawatt-days per ton of uranium obtained from a uranium slug. It should not be taken that any of the slugs in any of the reactors, whether they required modification or not, will remain in the piles for a time different from that under the original programme. Information on high irradiation is required and we cannot wait for developments at Hinkley Point, which is not yet in operation; there is nothing to stop certain elements being left in the Generating Board's reactors to see if they can be burnt to the desired length. For the export trade we are simply concerned with the prices at which the slugs will be sold and bought back, and Sir Ian thought the overseas purchasers may well prefer to get rid of their slugs at a short rate of irradiation rather than otherwise. That price must be settled as part of the contract, and in conclusion Sir Ian, pointing out that the changes are marginal and that plutonium is produced initially in this type of reactor, emphasized that the costs on the defence side must be incurred anyhow, and expressed the hope that no suggestion would get abroad that we are making fundamental changes in these reactors and hinder the development of a promising and vital civil nuclear programme.

Developments in Nuclear Energy

In a written answer in the House of Commons on July 14, Sir Ian Horobin, for the Minister of Power, stated that the Safety Branch of the Atomic Energy Authority is being strengthened in accordance with the recommendations of the Fleck Committee, and the Government is preparing legislation to implement the policy of licensing and inspection which he had outlined on February 10. Also in a written answer, the Prime Minister said on July 15 that experimental work on thermonuclear fusion at the Atomic Weapons Research Establishment at Aldermaston is directed towards a better understanding of the mechanism by which high gas temperatures can be achieved. The encouraging results to date do not alter earlier predictions about the probable time-scale of the development of thermonuclear power. The Atomic Energy Authority is recruiting some additional staff for this work. Replying for the Prime Minister on July 17, Mr. R. A. Butler said that the agreement under negotiation with the Euratom Commission is likely to contain provisions similar to those in the agreement with the Italian Government, which provide for the supply of fuel by the United Kingdom and for assistance in the manufacture of fuel elements in Italy in due course. The role of the Euratom supply agency is a point to be taken into account in these negotiations and the Commission has given assurances that it does not intend to erect any obstacles to the development of nuclear power in its member countries. Pressed further on the point, Mr. Butler said he hoped that British technical contact with the Euratom Commission would be close.

Engineering Research

In an oral reply in the House of Commons on July 1, Mr. H. Nicholls, Parliamentary Secretary to the Ministry of Works, representing the Lord President of the Council, said that to get its research results across to members, particularly at the shop-floor level, the Production Engineering Research Association had developed an effective liaison and advisory service, on which one-third of its resources were spent. Short instructional courses on new production techniques were held in the Association's Melton Mowbray laboratories, which had been attended by about 1,650 persons during the past year, and a mobile unit had provided 150 practical demonstrations in members' works. About 3,000 technical inquiries were answered each year. He undertook to see whether the connexion between East Kilbride, engineering firms and universities in Scotland was sufficiently close. In reply to a further question, Mr. Nicholls said that for some years the Mechanical Engineering Research Laboratory had sponsored at universities, and itself conducted, research on heat transfer under various conditions of steam condensation and it had been demonstrated that condensation of steam on cooling surfaces as separate drops had great advantages in speed over normal film condensation. Chemicals had been developed which when applied to brass or copper surfaces produced this 'drop' condensation, and the method had been tried to some extent in industry. If it proved really successful the size of condensers would be halved.

Distribution of Industry

In introducing the Distribution of Industry (Industrial Finance) Bill, which was generally welcomed and received an unopposed second reading in the House of Lords on July 15, Lord Mancroft said that since the Distribution of Industry Act was passed in 1945 the pattern of unemployment in the country had changed. In some places in the development areas Government-financed factories were at present themselves providing work for nearly 200,000 people, apart from work provided by firms attracted to those areas without Government assistance; but in other places outside the development areas unemployment had become high and might remain high. The Government believed it was as important to assist those places as to assist the development areas, and accordingly the Bill proposed to extend the powers given to the Treasury under the present Act to make grants or loans to industry in the development areas to include places outside those areas where the Board of Trade was satisfied that the money would assist to reduce a high rate of unemployment which might otherwise be expected to continue. The Bill would also enable grants or loans to be made to undertakings engaged in trade or business as well as in industry, and Lord Mancroft explained that the Bill purposely did not define either the places or the undertakings which would be covered. This was to ensure the maximum flexibility, and Lord Mancroft said that banks, insurance companies, hire purchase companies, hotels and office organizations generally might be included. He undertook to look carefully into a technical point raised by Lord Conesford regarding the bearing of the Bill on the proper distribution of industry. Viscount Hall, in welcoming the Bill, quoted the Board of Trade estimate that expenditure on factory building of £70 million under the original Act over twelve years represented 90 per cent of expenditure under that Act and that loans had totalled £6,900,000.

Fuel Abstracts

Asked for a statement in the House of Commons on *Fuel Abstracts* on July 2, Mr. H. Nicholls, as representing the Lord President of the Council, said in a written answer that before deciding to discontinue *Fuel Abstracts* the Department of Scientific and Industrial Research consulted the Ministry of Power, the National Coal Board, the British Coal Utilization Research Association and other organizations. Careful examination showed that the various sections of *Fuel Abstracts* were covered wholly or in part by other abstracting organizations. Discussions have taken place with the National Coal Board as to ways and means of arranging for abstracting organizations in Britain to extend their present coverage and for the provision of some form of joint index. The Society of Chemical Industry is increasing the coverage of abstracts within its field of interest, while the Institute of Fuel is considering the possibility of issuing collected abstracts of fuel literature. The Department had had arrangements with abstracting organizations which do not make their abstracts directly available to the general public, whereby abstracts of fuel literature could be published in *Fuel Abstracts*, and there was no reason to suppose that similar arrangements could not be made by any other organization which publishes collected abstracts of fuel literature.

International Geophysical Year: Meeting in Moscow

The fifth meeting of the Special Committee (C.S.A.G.I.) of the International Geophysical Year is being held during July 29–August 9 in the Moscow State University. The meeting is reviewing the achievements of the International Geophysical Year since its commencement on July 1, 1957, and also the scheme now in operation for the deposition and exchange of results between the three data centres set up for each of the International Geophysical Year disciplines. During the course of the meeting there will be many discussions of a technical nature concerning preliminary results, and in addition there will be a symposium lasting several days concerning the rocket and artificial Earth satellite programme. A meeting of the Special Committee for Antarctic Research set up by the International Council of Scientific Unions is to consider research programmes in the Antarctic region after the closing of the International Geophysical Year programme on December 31, 1958.

Tax Concessions on Subscriptions to Learned Societies

When the tax concessions to individuals on their fees and subscriptions to learned societies and professional bodies, contained in the Finance Bill, were debated in the House of Commons on July 17, objections were raised to the limitation of the concession to bodies which were "not of a mainly local character". Mr. J. E. S. Simon, Financial Secretary to the Treasury, explained that the Inland Revenue had already to examine the claims of some 3,000 national societies and to extend it to all the local bodies would involve an administrative task in which the benefit to individuals would be out of all proportion to the expense involved. He fully appreciated the claims of many local societies but insisted that the relief to the individual tax-payer had to be balanced against the cost to the general body of tax-payers. He undertook, however, to put the views expressed before the Chancellor of the Exchequer. Mr. Simon also said that it was not a condition of relief that the employer should stipulate membership of a professional body; it was sufficient that the registration should be a condition for the performance of the claimant's duties. The views of the employer were no longer relevant. He also added that the clause would not be construed narrowly by the Inland Revenue, but in a common-sense way, with a desire to help professional men who could bring themselves fairly within its terms.

Journal of Nuclear Energy

It has been announced that the *Journal of Nuclear Energy* is shortly to be issued in two parts (*A* and *B*) dealing respectively with basic reactor science and reactor technology. Part *A* will continue to be published monthly with little alteration and will consist of papers dealing with the scientific, biological and economic aspects of nuclear energy. Part *B* will be published quarterly and the first issue will appear in time for the Second Geneva Conference. It will be devoted to technological subjects contributing to the development of nuclear energy for peaceful purposes and will contain papers on mathematics (including computing for design purposes); applied physics; fuel processing and plant criticality; heat transfer; fuel element design and fabrication; and other scientific aspects of the construction and operation of nuclear reactors. The editors direct attention to three important characteristics of Part *B*: the international character of the journal; the high scientific and professional standard; and the short publication time. Both parts of the journal will contain translations of relevant papers published in the Russian journal of atomic energy, *Atomnaya Energiya*.

Progress in Rubber Technology

The current annual report on the "Progress of Rubber Technology" (edited by Dr. T. J. Drakeley, Pp. xi+134. Cambridge: W. Heffer and Sons, Ltd., 1958. 25*s*.), issued by the Institution of the Rubber Industry, gives a brief but reasonably detailed review of developments up to the end of 1957. All aspects of the industry, scientific, technical and economic, are included, and the arrangement in the form of short chapters on specific topics makes for easy reading and quick reference. The subject-matter is not limited to rubbers, but includes materials, such as fibres and plastics, which are used either in association with rubbers or as alternatives to them. Every branch of the industry, including tyres, belting, cables, footwear, cellular rubber, flooring and roads, is covered, and other chapters deal with subjects of more general scientific interest, though these form only a small proportion of the whole. The main value of this publication is that it enables the reader to keep in touch with developments outside his own speciality, and to obtain a quick appreciation of general trends in the industry. Foremost among these is that—in spite of the continued advance of synthetic rubbers and of materials designed to satisfy particular technical requirements—the total demand is expanding at such a rate that the market for natural rubber has remained remarkably stable, and new planting is in progress in various parts of the world. There appears also to be a lively development of scientific interest in new ways of using natural rubber, particularly in conjunction with other polymers, to meet the threat of competition from the synthetics.

New Floristic Studies

The physiography of the vast and interesting region comprising the Canadian Arctic Archipelago has recently been described in a publication issued by the National Museum of Canada, "Illustrated Flora of the Canadian Arctic Archipelago", by A. E. Porsild (National Museum of Canada, Bulletin No. 146: Biological Series No. 50. Pp. iii+209. Ottawa: Queen's Printer, 1957. 2 dollars). The Bulletin also deals with the soils and plant habitats of the region; and numerous illustrations, species distribution maps and keys are provided. In all, some 340 species and major geographical races of flowering plants and pteridophytes are described. The author records that, in this and other floristic studies of the region which he has undertaken, the Canadian Arctic is defined as including all the land area—some 900,000 sq. miles—which lies north of the treeline, the latter, broadly speaking, following the 10° C. isotherm for the warmest month.

A rather different work, issued by the United States National Museum, Smithsonian Institution, Washington, D.C., as U.S. National Herbarium, 33; 1957, is "The Bromeliaceae of Colombia", by L. B. Smith (pp. vi+311. Washington, D.C.: Government Printing Office, 1957). This family is, of course, very abundantly represented throughout the American tropical and sub-tropical regions. Thus the author of the present monograph notes that, during the past twenty years, the record of known Colombian species has been practically doubled, some 372 species being now known. The Colombian Bromeliaceae fall into three groups: on the criteria of floral morphology, the Andean group is primitive, and the Guiana Highland and Amazonian groups are derivative. The rich representation of two species, *Tillandsia* and *Puya*, have led the author to the tentative conclusion that the family may have originated in Colombia.

Perkin Centenary Trust Awards

THE Perkin Centenary Fellowship has been awarded to Mr. Dennis Balmforth, of Messrs. Courtaulds, Ltd., Coventry, and will be tenable from October 1 in the Department of Colour Chemistry at the University of Leeds. Perkin Centenary Scholarships have been awarded to Mr. Brian Higginbottom, assistant chemist in the laboratories of the Bleachers' Association, Ltd., tenable at the College of Technology, Loughborough, and to Mr. W. K. McCourt, laboratory foreman with Messrs. Courtaulds, Ltd., Carrickfergus, tenable at The Queen's University, Belfast. Arrangements have also been made for a Perkin Exchange Lectureship whereby short visits will be exchanged between Prof. A. J. Birch, of the University of Manchester, and Prof. V. Prelog, of the Eidgenössische Technische Hochschule, Zurich. Prof. Birch will visit Zurich in September 1958, and it is hoped that Prof. Prelog will return the visit in the following year. Each will deliver one or more lectures during the visit, which will last about two or three weeks.

The programme of awards for the year 1959–60 will include one Perkin Centenary Fellowship, valued at not less than £600 a year, which is available to a graduate for higher study, and two Perkin Centenary Scholarships, of £300 a year each, which are intended to give young persons employed in the industries concerned with the manufacture or the application of colouring matters the opportunity of full-time education at a university or technical college. Further nominations are not at present invited for the Perkin Exchange Lectureship. In the place of this award the Trustees will consider making one or more Perkin Centenary Trust Travel Grants to enable teachers concerned in the study of any aspect of the manufacture or application of colouring matters at a university or technical college to make short visits to comparable institutions overseas in order to widen their experience. The Perkin Centenary Trust was established as a memorial to the discovery in 1856 of the first important synthetic dyestuff, mauveine, by William Henry Perkin. The secretary to the Trustees is Dr. J. R. Ruck Keene, to whom inquiries relating to the awards should be addressed, at the Chemical Society, Burlington House, London, W.1.

Announcements

SIR JOHN STOPFORD, lately vice-chancellor of the University of Manchester and emeritus professor of experimental neurology, has been created a baron under the provisions of the Life Peerages Act.

PROF. O. T. JONES, emeritus professor of geology in the University of Cambridge, has been awarded the Liverpool Geological Society Medal in recognition of his varied contribution to and lasting influence on the science of geology over the past half century, and particularly of his illuminating work on the Silurian of North Wales.

THE Council of the British Institution of Radio Engineers has announced the award of a number of premiums for original publications and prizes for outstanding performances in the Institution's graduateship examinations in 1957. The Clerk Maxwell Premium—the premier award for the most outstanding paper published in the Institution's *Journal* during 1957—is to go to Dr. T. B. Tomlinson for his paper, "Principles of the Light Amplifier and Allied Devices", based on work carried out at the research laboratories of the General Electric Company; he is now with Computer Developments, Ltd.

THE work in progress at the National Chemical Laboratory may be seen during the open days to be held on October 21 and 22. Applications from firms for invitations to the sessions should be sent to the director not later than September 20. Firms already on the mailing list for invitations need not re-apply. Further information can be obtained from the National Chemical Laboratory, Teddington, Middlesex.

THE fourth International Conference on Electron Microscopy, organized by the Deutsche Gesellschaft für Elektronenmikroskopie, will be held in Berlin during September 10–17. Further information can be obtained from Prof. E. Ruska, Berlin-Dahlem, Faradayweg 4–6.

THE Indian Central Fuel Research Institute is organizing a symposium on "The Nature of Coal" during February 9–11. Papers, not exceeding 3,000 words in length, with their abstracts, should reach the Director, Central Fuel Research Institute, P.O. Fuel Research Institute, Dhanbad Dist., Bihar, India, not later than October 31.

An informal discussion on "Isotopic Exchange Reactions", sponsored by the Faraday Society, will be held in the School of Chemistry, University of Leeds, on September 25 and 26. The programme will include applications of radioactive and stable isotopes to the study of liquid, gaseous and solid-gaseous systems. Further information can be obtained from Dr. D. R. Stranks, School of Chemistry, The University, Leeds, 2.

A COURSE on the control and instrumentation of reactors is to be held at the Harwell Reactor School during October 6–11. The fee for the course will be 25 guineas exclusive of accommodation. Further information can be obtained from the Principal, Reactor School, Atomic Energy Research Establishment, Harwell.

ERRATUM. In *Nature* of July 19, p. 158, under "University News: Bristol", for "Dr. J. W. F. McOmie" read "Dr. J. F. W. McOmie".

MECHANICAL PROPERTIES OF WHISKERS AND THIN FILMS

ON March 17–19 some sixty scientists met at the Cavendish Laboratory, Cambridge, and Tube Investments Research Laboratories, Hinxton Hall, for an informal discussion of nineteen papers on "The Mechanical Properties of Whiskers and Thin Films", invited from universities and industrial research laboratories in Great Britain and the United States. The main purpose of the meeting was to review the present state of knowledge on the high mechanical strength observed when one or two dimensions of a test specimen are reduced to a small value. The organizing committee consisted of Dr. F. P. Bowden, Mr. J. E. Gordon and Dr. J. W. Menter.

D. Turnbull (General Electric Co.) opened the proceedings with a survey of mechanisms of whisker growth. Whiskers can be grown either by spontaneous extrusion or by growth into physically or chemically supersaturated media. The former are very strong in bend tests (Galt and Herring) but not in tension tests. Plausible dislocation mechanisms for the observed growth from the root have been advanced by Eshelby, Frank and Seitz.

By contrast, whiskers appearing in physically supersaturated media grow at the tip although they appear to be nucleated at singularities on the substrate. A typical example is mercury, which, after an initial period of growth to a considerable length at a constant thickness of about 100 A., begins to thicken abruptly. Sears suggested that growth occurs by the action of a single axial screw dislocation, and this is supported by the field emission studies of Gomer. Whiskers grown in this way are strong both in bend and tension tests.

Similar mechanical properties are observed in whiskers grown from chemically supersaturated media, which have been extensively studied by Brenner. The growth mechanism is not clearly understood, but Frank has suggested that in some cases it may be controlled by the rate of chemical reduction at the tip or root.

Metal Whiskers

A number of papers then followed on the mechanical properties of metal whiskers. S. S. Brenner (General Electric Co.), in a paper on the plastic deformation of metal whiskers, first summarized the observations of himself and others on the elastic behaviour of whiskers. Elastic strains from 1 to 5 per cent have been reported with a maximum tensile strength of 1,400 kgm./mm.^{2} in an iron whisker about 2μ in diameter (but see Bacon below). Brenner has found that the plastic deformation of copper, silver and iron whiskers occurs by the motion of a Lüders band at a stress sometimes as small as 1 per cent of the yield stress. The local plastic strain in the Lüders band remains constant at values ranging from 0·25 to 0·40 during propagation, depending on the diameter of the whisker. Cross-slip can readily occur at these strains, suggesting that slip may extend along the whisker by a double cross-slip mechanism. Lüders bands are more difficult to observe in iron since extensive local deformation occurs within the band. This local slip is very sensitive to the applied stress, with the result that at high stresses fracture occurs before much of the whisker has slipped. No appreciable part of the elastic strength of whiskers can be recovered by annealing at temperatures up to 600° C. Creep has been observed in iron whiskers and a linear region can usually be observed in which the creep-rate varies roughly exponentially with the applied stress.

N. Cabrera described experiments on the creep of vapour-grown zinc and cadmium whiskers carried out at the University of Virginia with H. H. Hobbs and P. B. Price. An initial non-linear region is observed in the stress – strain curve followed by yield at strains of the order of 1 per cent. If the stress is maintained constant below yield for several hours, creep is observed, the initial creep-rate increasing with the applied stress. A saturation value is finally reached, and once creep has been exhausted at a particular level no more creep is observed at any other level. These results are tentatively interpreted as due to pinned-down dislocations (of the order of 10^8–10^9 cm.$^{-2}$) already present, most of which are pushed out of the whiskers during the creep process, leaving a much more perfect crystal, which then yields at higher stresses (1·5–2 per cent strain). The pinning may be associated with impurities which may be present in concentrations of the order of 10^{-4} impurity atoms per pure atom if the residual resistance observed at liquid-helium temperature is interpreted as due to impurities.

From optical and electron microscope replica studies of copper whiskers, G. A. Geach and P. E. Charsley (Associated Electrical Industries Research Laboratories, Aldermaston) deduced that slip in the Lüders band occurs on only one system, with the implication that the band is not propagated by a double cross-slip mechanism. In whiskers with a $< 211 >$ axis it appears that the slip system in the Lüders band is not that corresponding to the maximum resolved shear stress. The slip distance is observed to depend on size. 5-μ whiskers showed slip steps with up to 0·7μ glide, whereas the amount of glide was only a few hundred angstroms or less for the slip steps on a 20-μ whisker.

The surface characteristics of copper whiskers have been studied by D. Vermilyea (General Electric Co.). D. Turnbull, in presenting this work, suggested that both the physical and chemical behaviour of whiskers free from dislocations except for an axial screw might be unique if their side-walls are perfectly smooth and densely packed. Vermilyea has studied the overpotential required to discharge cupric ions or dissolve copper metal at the surface of copper whiskers. On bulk copper these processes occur at relatively small overpotentials (about 5 mV.) and apparently uniformly over the entire surface. However, overpotentials of about 100 mV. and 20 mV., respectively, are required to discharge cupric ions or dissolve copper metal at the surface of a 3-μ copper whisker, and the electrolytic action occurs only at a few small areas not including the whisker tip. These observations suggest that the surface of these whiskers may indeed be very smooth and with certain reservations may be taken to imply that the density of dislocations in the whisker may be very low.

G. A. Bassett (Tube Investments Research Laboratories, Hinxton) briefly described a new technique for revealing surface steps down to atomic dimensions, which might be useful for studying the surface perfection of whiskers. Evaporated gold layers are found to be nucleated preferentially along step edges on some ionic crystals. These nuclei are detached by means of a carbon film and used as a 'decoration replica' for observations on surface-step structures. It is not known whether similar effects could be obtained on metallic surfaces.

Some qualitative evidence on the dislocation structure in iron whiskers 10–200μ in diameter with axes in < 100 >, < 110 > and < 111 > directions was presented by R. V. Coleman (General Motors Corp.). Well-defined etch pits connected with dislocations are observed on {100} faces using 4 per cent picral or 2 per cent nital etchants. Perfectly oriented {100} surfaces do not in general develop etch pits, although random groups of pits are observed on some other surfaces. These are of two types: a 'sharp-bottomed' pit which develops rapidly, and a rounded flattened pit which develops more slowly. Larger numbers of the former develop after plastically deforming the whiskers, the density increasing with deformation and remaining constant with time for a given deformation. After annealing at 850° C. for some hours and etching, polygonized and other arrays of dislocations can be seen.

Non-metallic Whiskers

C. C. Evans, D. M. Marsh and J. E. Gordon (Tube Investments Research Laboratories, Hinxton) described observations on the properties of non-metallic whiskers of hydroquinone, nickel sulphate, sodium chloride, potassium chloride and potassium permanganate. Optical studies show that growth occurs from an initial very thin 'leader' crystal in the micron range, which then thickens by the longitudinal spreading of growth layers. A needle habit can be induced in sodium chloride by the addition of very small quantities of polyvinyl alcohol or sucrose to a saturated aqueous solution. Mechanical tensile tests on crystals of sodium chloride between 1 and 200μ^2 grown in this way have been made with a special testing machine developed by Marsh. Below 2μ^2 the whiskers are fully elastic up to fracture at a strain of about 1 per cent, but with increasing size the elastic limit falls and an increasing region of plastic deformation is observed. In the ductile region, slip bands and local necking are observed, and the largest specimens show some work hardening. The machine is not at present suitable for detecting a sharp yield point.

P. E. Charsley (Associated Electrical Industries Research Laboratories, Aldermaston) has investigated the structure of whiskers of sodium and potassium chlorides by electron microscopy and diffraction. Sodium chloride shows a predominant < 100 > orientation with occasional < 110 >, whereas potassium chloride whiskers are invariably < 110 >. The most common shape of sodium chloride whisker is bounded by two parallel {100} planes, the other surfaces being irregular, since the edges of growth layers appear to originate in the centre of the {100} faces. These whiskers frequently disintegrate during direct examination under the electron microscope, the larger ones revealing a substructure bounded by < 100 > directions and the smaller (a few tenths of a micron in diameter) showing no regular substructure. This dependence of the substructure on size is correlated with evidence for a layer structure obtained from carbon-replica studies, and it is suggested that layer growth results in lattice imperfections which may be the cause of the decrease in tensile strength with increasing diameter observed by Gyulai.

A. Berghezan (European Research Associates) presented a paper by R. Bacon (National Carbon Research Laboratory, Union Carbide Corp., U.S.A.) describing some interesting observations on graphite whiskers grown by a high-pressure arc process. Whiskers 0·5–5μ in diameter and several millimetres in length show a remarkably high fracture strength of 2,000 kgm./mm.^{2} at an elastic strain of 2 per cent. Most of these whiskers exhibit a ribbon-like form which are often single crystal over their entire length, with the *c*-axis perpendicular to the axis of the whisker. Some whiskers are cylindrical, but again X-ray examination shows that the *c*-axis is normal to the axis of the whisker in all azimuths, suggesting a structure consisting of one or more concentric tubes each of which is essentially a large sheet, many atomic layers thick, rolled up into a tight spiral scroll. Growth is thought to occur by addition of carbon to the spiral edge of the rolled-up sheet so that the whisker elongates rapidly (10 in./hr.). The elastic modulus of these whiskers is about 100 times that of bulk polycrystalline graphite.

Some aspects of the theory of dislocations in whiskers were considered by J. D. Eshelby (Department of Metallurgy, Birmingham) and J. P. Hirth (Carnegie Institute of Technology). The former described a method for calculating the twist which an axial screw dislocation produces in a whisker of arbitrary cross-section, and briefly discussed the stability of the dislocation. Hirth considered the possibility of thermally activated slip of dislocations out of metal whiskers, as a possible mechanism for the cessation of whisker growth. Whiskers with radii less than a critical value will not retain a single axial dislocation. Above the critical radius the dislocation will slip out only if it has an edge component of about 0·3 times the Burgers vector with respect to the axis of the whisker. The effects on whisker morphology predicted by this mechanism were shown to be consistent with observation.

Most of the evidence on crystalline whiskers seemed to indicate a fairly definite dependence on size of mechanical properties. Earlier work on non-crystalline glass fibres followed the same trend, but more recently it has been shown that if care is taken to avoid surface damage, strength is virtually independent of fibre size. The problem of size, strength and structure in glass was discussed in a paper by M. E. M. L. Parratt, D. M. Marsh and J. E. Gordon (Tube Investments Research Laboratories, Hinxton). On the assumption that failure is associated with surface defects, an improved sodium decorating technique has been used to study surface crack patterns and definite correlations have been made between their extent and the mechanical strength. These crack patterns present on the surface of all fire-polished glass seem to control the mechanical strength up to at least 3 per cent strain. The origin of these cracks is not clear. Electron microscope studies on thin films of glass showed that devitrification could lead to cracks, but an alternative source was abrasion, the susceptibility to which may be associated with the state of stress of the surface.

The importance of the surface condition was emphasized by D. G. Holloway (University College of

North Staffordshire), who has found that the bending strength of 60–120-μ 'Pyrex' fibres is larger by a factor of 5–6 when drawn and tested under high vacuum compared with those drawn and tested in air or those drawn in vacuum and tested in air. The drop in strength was attributed to atmospheric attack on the surface.

Thin Films

D. W. Pashley (Tube Investments Research Laboratories, Hinxton) has studied the tensile deformation of single-crystal films of gold in (111) orientation, 500–2000 A. in thickness, inside the electron microscope. No movement of the grown-in dislocations (10^{10}–10^{11} cm.$^{-2}$) was observed as the strain was increased to about 1 per cent, and this strain was confirmed as elastic by measurements on electron diffraction patterns from the strained film and by means of stress-strain measurements carried out externally by D. Marsh.

At an elastic strain of about 1 per cent the film was observed to fracture by the propagation of a highly localized region of plastic deformation along the film corresponding to slip on $(11\bar{1})$, $(1\bar{1}1)$ and $(\bar{1}11)$ planes. This led to complete fracture of the thinner films, but with thicker films short regions where fracture occurred were joined by regions of less localized plastic deformation.

T. Evans (Tube Investments Research Laboratories, Hinxton) described experiments in which similar single-crystal films of gold, gold/palladium, rhodium and platinum oriented on substrates consisting of single crystals of silver were deformed as a result of tensile stress applied to the substrate. In this situation the film may become deformed plastically with the substrate up to large deformations, provided dislocations from the substrate are able to pass into and through the film. The important determining parameters are the relative lattice misfit between film and substrate and the relative elastic moduli. Examination by transmission electron microscopy of films stripped after deformation showed that gold and gold/palladium accommodated the strain of the substrate by slip, whereas platinum and particularly rhodium films had many cracks following the traces of slip planes in the substrate, implying that the film had cracked locally due to the stress concentration arising from piled-up groups of dislocations on the substrate slip planes immediately below the film.

P. B. Hirsch and M. J. Whelan (Cavendish Laboratory, Cambridge) considered the factors determining the strength of thin metal foils with free surfaces, inferred from their direct observations in the electron microscope. Moving dislocations leave behind traces at the top and bottom surfaces, which are thought to be surface dislocations held up at the interface between the metal and an oxide or other type of surface film.

For a thick oxide film the stresses required to move dislocations approach the critical Frank–Read stress of the dislocation line in the metal film. Estimates of this stress from curvature of the line suggest that some dislocations move under stresses of about $G/1{,}000$ in foils about 1000 A. thick. Although in favourable circumstances it is expected that a Frank–Read source might operate, no direct observation of such a source has been made.

However, dislocations have been observed to nucleate near the edge of a thin foil. The dislocations appear to be half loops which have run in from the edge. Following a suggestion by Cottrell, nucleation of dislocations in a wedge crystal has been considered theoretically. It is found that, for a dislocation with Burgers vector in the surface of a thin foil with a wedge angle of 0·1 radian, the activation energy for nucleation is about 1 eV. at stresses of the order of $G/150$. This theory may possibly account for the observed nucleation in the majority of cases.

B. A. Bilby (Department of Metallurgy, Sheffield) also considered theoretically the nucleation of slip in thin plates, using solutions of elastic equations given by Leibfried and Dietze and by Eshelby and Stroh. For a long straight screw dislocation parallel to the plane of the plate a significant reduction in the activation energy occurs only at very high stresses or for very thin plates. A calculation was also made for the introduction of a pair of screw-dislocations lying normal to the plate, with results confirming in order of magnitude those of Hirsch and Whelan for the thin wedge. The energy of steps forming and disappearing on the surfaces as the dislocations are introduced plays an important part, but more detailed models are required to assess their effect quantitatively.

J. Nutting and D. G. Brandon (Department of Metallurgy, Cambridge) have tested iron foils, 99·97 per cent pure, in tensile deformation, with different thickness and grain size. The yield stress and extent of yield decreased and the rate of work hardening increased with decreasing foil thickness (down to less than 30μ). In coarse-grained foils the yield phenomenon was less affected than in the fine-grained. Factors affecting the behaviour of the foils include stress concentration due to local variation in thickness, decrease of constraints on individual grains, triaxial stress distributions resulting from surface rumpling during deformation and possible changes in the dislocation mechanism for deformation. No evidence for the last had been found by transmission electron microscope studies on thinned foils, although more deformation and kink bands and relatively few slip lines are seen on the surface of the thinner foils.

R. B. Nicholson (Department of Metallurgy, Cambridge) showed that the coherency strains associated with Guinier–Preston zones in aluminium/4 per cent copper alloys could be made directly visible in thin films of the alloy studied in the electron microscope and discussed their effect on the age-hardening characteristics of this alloy. G. Thomas (Department of Metallurgy, Cambridge) has studied precipitation phenomena and dislocation structures in thin foils of aluminium/magnesium/zinc alloys in the electron microscope. When previously aged beyond maximum hardness it is possible to cause movement of dislocations in the foils by heating in the electron beam. The chief sources of dislocations appear to be the grain boundaries. The stresses obtained by heating appear to be insufficient to move dislocations through precipitates.

As was intended, the papers given were essentially accounts of work in progress, and it is therefore not easy to give a considered view of the field as a whole. Explanations of the high strength of whiskers start from two conflicting assumptions about their microstructure. Some whiskers are undoubtedly highly perfect and it is reasonable to expect these to show a long elastic range. Whether surface perfection is essential for strength in addition to interior perfection depends on the view taken of the possibility of nucleation of dislocations or cracks from surface irregularities. The alternative view is that whiskers may well be imperfect, but high strength may still be observed because of the pinning of dislocations and inhibition of sources due to the small dimensions of the specimen. Both the latter strengthening mechanisms have been shown to be plausible for thin films from direct observation in the electron microscope, and it would be valuable to have more direct information of a similar nature about whiskers. Equally it would be valuable to have much more information about the relation between strength and thickness for thin films.

It is important to know more about changes in mechanisms and modes of deformation with thickness and also whether a small thickness alone is adequate to achieve high strength. The structure of the film arising from the particular method of preparation may also turn out to be important.

J. W. MENTER

CHEMISTRY OF PLANT PRODUCTS

THE Royal Australian Chemical Institute's Western Australian Branch, in co-operation with the University of Western Australia, held a symposium on "Plant Products" at the Chemistry Department of the University on March 20 and 21. The first day was devoted to general and technological papers and the second mainly to structural chemical investigations. About 45 members and guests attended the two sessions.

After introductory remarks by Dr. D. E. White, president of the Branch, who welcomed the visitors, Dr. J. R. Price (Division of Industrial Chemistry, Commonwealth Scientific and Industrial Research Organization, Melbourne) outlined the development of phytochemistry in Australia, from the pioneers, like the Surgeon of the First Fleet, to its present flourishing state. Work in this field is carried on in most of the Universities and also by the Commonwealth Scientific and Industrial Research Organization. After discussing briefly the role of these institutions, Dr. Price summarized the scope, organization, objectives and potentialities of current work in the Division of Industrial Chemistry. Mr. R. H. Pearce (Kwinana Chemical Co., Kalamunda) described the application of solvent extraction and chromatography to the separation of fractions from *Xanthorrhoea* resins. Variations with species and age of the resin were discussed and some components were found to be unstable in light and air. The techniques used appear much more promising than those previously used in attempts to isolate compounds from this resin.

An account of the use of growth regulators in viticulture was given by Mr. L. T. Jones (Department of Agriculture, Perth), who described the effect of hormone spraying in place of the obsolete and harmful practice of cincturing vines. Local research work illustrated the superiority of such hormones as PCPA, 2,4-dichloro- and 2,4,5-trichloro-phenoxyacetic acids and gibberellic acid, resulting in increased production, improved fruiting, prevention of preharvest fruit drop and the killing of unwanted vines. Reference was made to the disadvantages of hormone spraying, for example, damage to bunches and vines, but these were due to incorrect application of the spray. Mr. Jones pointed out that gibberellic acid (not strictly a hormone), had been used experimentally only recently, and the results obtained suggest a promising future for the use of this material in viticulture. A striking contrast between the sizes of bunches on treated and untreated vines was shown in colour slides.

Mr. W. E. Hillis (Division of Forest Products, Commonwealth Scientific and Industrial Research Organization, Melbourne) discussed chemical aspects of the sapwood-heartwood transformation, referring particularly to the increased polyphenolic content of the heartwoods of Australian timber trees. These components, which contribute to durability, may be derived from the cambium, the leaves or the starch in the sapwood, and evidence indicates that an appreciable portion arises from the latter. The significance of the shikimic acid content of *Eucalyptus sieberiana* leaves of different sizes, before and after shading, was discussed.

Dr. H. Jakobs (Leederville, W.A.) described how chemical research had made possible much of the agricultural development in the Dutch East Indies. He exemplified this in detail by reference to the tea industry, which is now of major importance in Indonesia.

Dr. D. E. White discussed a study made with D. K. Dougall on the 'primary' tars, obtained by distillation of jarrah and karri sawdust *in vacuo*. Among the compounds isolated catechol, 2 : 6-dimethoxyphenol, 1 : 2 : 3-trihydroxybenzene, 5-methylfurfural and D-glucosan (1 : 5)β(1 : 6) were identified. Decomposition of the latter was responsible for the low decomposition temperature of the tar.

The second day's proceedings opened with a paper on the chemistry of stock poison-plants by Dr. C. C. J. Culvenor (Division of Industrial Chemistry, Commonwealth Scientific and Industrial Research Organization, Melbourne) read by Dr. J. R. Price. The liver-damaging pyrollizidine alkaloids and their N-oxides isolated from Compositae, Leguminosae and Boraginaceae were described with special reference to the recognition of monocrotaline from *Crotalaria retusa* as the cause of Kimberley horse disease. Recent work on other *Crotalaria* spp. was also discussed.

Dr. P. R. Jefferies (Chemistry Department, University of Western Australia) outlined the principles of gas chromatography and showed how it could be used for the quantitative analysis of simple mixtures. Complex mixtures as found in essential oils can be studied qualitatively, first on the whole oil, and then on distillation fractions. In this way the isolation of pure compounds is greatly facilitated and the presence of high-boiling components can be easily detected.

The constitution of the sesquiterpene alcohol globulol was discussed by Mr. G. J. H. Melrose in a joint paper with P. R. Jefferies and D. E. White. He described new sources of this alcohol in Western Australian Myrtaceae, and the synthesis of an epimer by the reaction of methyl magnesium iodide with apoaromadendrone. This alcohol also affords aromadendrene on pyrolysis of its 3 : 5-dinitrobenzoate. Hence the junction of the 5 and 7 membered rings in aromadendrene must be the more stable (*cis*) type. Other features of the stereochemistry of globulol and *epi*-globulol were also discussed and evidence for the attachment of the *cyclo*propane ring to C_6 and C_7 was outlined.

The chemistry of *Lunasia* alkaloids was discussed by Dr. J. R. Price, who compared the American work on *L. amara* with that done in the Commonwealth Scientific and Industrial Research Organization on *L. quercifolia*. In addition to the tertiary bases, lunacrine and lunacridine, water-soluble bases were present, the major component of which analysed for $C_{17}H_{22}O_3N^+$. A possible structure for this compound, which forms lunacridine when treated with alkali, was presented.

Mr. J. O. Knight presented the final paper in collaboration with A. R. H. Cole, D. C. Shaw and D. E. White, on triterpenoid constitutents of the Myrtaceae. After discussing the common occurrence of betulic acid in members of this family he dealt with the structure of melaleucic acid. The structure originally assigned (3β-hydroxylup-20(29)–en–25 : 28-dioic acid; *Chem. and Indust.*, 926; 1956) cannot be correct since the lactone which was assumed to involve the 3-hydroxyl and the 25-carboxyl affords a tertiary hydroxyl group on reduction with lithium aluminium hydride. The second carboxyl group must be on C_{26} or C_{27} and its lactonization involves re-arrangement. Means for distinguishing between these possibilities were discussed.

D. E. WHITE

THE INSTITUTE OF BIOLOGY

ANNUAL CONVERSAZIONE

THE annual conversazione of the London Branch of the Institute of Biology was held at University College on the evening of July 3. Prof. G. P. Wells and Dr. K. Mellanby (chairman of the London Branch) received members and their guests in the North Cloisters of the College. A large number of exhibits was on display in the Zoology Department, by courtesy of Prof. Wells.

The range of activities of this year's guest Society, the Botanical Society of the British Isles, was well shown by its exhibit. Of particular interest was its progress in the scheme to produce a map of the distribution of British plants. The mass of data for this scheme has been reduced to a minimum of space by the use of a punched-card system, and it is hoped that an atlas of British plants will be produced in 1960. A related project has been undertaken by the British Naturalists' Association, whose exhibit illustrated their work on a phenological survey which will map the changes in the flora and fauna which occur during the year and also the fluctuations of longer period.

Hospital and Laboratory Supplies, Ltd., provided this year's trade-stand, which gave a sample of the comprehensive range of apparatus and materials which this firm can supply. Specimen publications of the Universities Federation for Animal Welfare and of the Institute of Biology were on display, and the Department of Extra-Mural Studies of the University of London had produced an exhibit to illustrate the work of the Department in the field of biology.

Aspects of the Falklands Islands Dependencies Survey biological research were shown, including the method of ageing individual seals by the annual increments of dentine or cementum in the teeth, and also illustrating work on the reproductive cycle of the southern elephant seal. The Ministry of Agriculture, Fisheries and Food provided a stand showing advances in food research and development, particularly in food dehydration, and its Infestation Control Division was represented by Mr. G. A. Brett's exhibit of a common tropical cockroach, *Pycnoscelus surinamensis*, which is occasionally imported into Britain.

In addition to the exhibits of organizations, a large number of exhibits had been provided by members and guests. Studies on pest control provided the basis of several of these. An example of a serious infestation of a house by the ant *Lasius brunneus* was found in 1957 (A. A. Green), and there is some evidence of an increased tendency for this ant to invade houses. Population studies of locusts (R. F. Chapman) have made it necessary to be able to separate the egg-pods of locusts from those of other species; various characteristics of the pod can be used. The way in which infestation in a bulk of grain causes heating (D. H. Burges) introduced a model showing the rate of development of colonies of the flat grain beetle (L. P. Lefkovitch), colonies of up to 550,000 individuals being produced in 4 months.

A more gradual example of population increase was shown by the frog *Rana ridibunda* (J. I. Menzies); 12 specimens were introduced into England in 1935, and their descendents have spread at the expense of the British *Rana temporaria* and now cover 120 square miles of S.E. England. New anatomical work on the classification of the lugworm genus *Arenicola*, which can be divided into two groups, was shown by Prof. G. P. Wells, with a map of the zoogeography of this genus. Two very different types of colour change in the Orthoptera were shown (K. H. L. Key), some acridids showing a physiological change from black to blue as a direct reaction to increasing temperature, while some phasmatids show centromorphic colour changes related to population density.

Some exhibits were concerned with genetical studies. Studies on finger-print patterns (S. B. Holt) have shown that the total ridge-count is determined by additive genes with an independent effect but without dominance. In the fungus *Aspergillus nidulans* (M. Mahoney and D. Wilkie) some spores give rise only to asexual colonies; this appears to be due to the loss of a self-replicating cytoplasmic unit. The rare genetically determined biochemical defect in man known as gargoylism (U. Mittwoch) can be detected by the presence of abnormal inclusions in the lymphocytes.

An exhibit of the different degrees of specificity of both the bacteria and the leguminous plant in their symbiotic relationship (P. S. Nutman) showed also the way in which different mutant strains make it possible to study how the relationship develops. New methods of studying the cellular constituents of yeast (A. A. Eddy) have resulted from the discovery that protoplasts can be prepared by treating yeast cells with certain digestive enzymes of the snail *Helix*.

Exhibits concerned with research techniques included the compact lightweight McArthur microscope, designed for field-work; new uses for cellulose acetate in the culture of anaerobic bacteria and in electrophoresis (W. H. Pierce); and the confining of insects to treated plants under controlled conditions, for use in insecticide screening (D. T. Saggers).

There were many other exhibits, of no less interest and attractiveness than those mentioned above, and the exhibits as a whole provided starting-points for the informal discussion and conversation between those present which are, after all, the prime purpose of a conversazione.

C. B. Cox

MARIAN SMOLUCHOWSKI

MARIAN SMOLUCHOWSKI, the great Polish theoretical physicist, died during the First World War on September 5, 1917, in Cracow, and a description of his life and work was published by A. Teske three years ago ("Marian Smoluchowski: His Life and Work". Polish State Scientific Publishing House, Cracow, 1955). However, for those not familiar with the Polish language, the brief account of Smoluchowski's career and of his contributions to the theory of probabilities in physics given in the article contributed by S. Ulam to the October number of *The American Journal of Physics* (25, 475; 1957) will be very welcome.

Smoluchowski was born in Vienna in 1872. His father was a Cracow lawyer who later became secretary of the Chancellery at the Court of the Emperor Francis Joseph. His mother, too, was well educated, and Smoluchowski was brought up in highly intellectual surroundings. He early showed an interest in science and he studied mathematics and physics at the University of Vienna, attending the lectures given by Boltzmann, Mach and others. He published his first scientific paper in his second year at the University, finally graduating with the highest honours. After a year in Paris working with Lipmann, he studied for a year in Glasgow under Kelvin and then spent a few months in the laboratory of Prof. Warburg in Charlottenberg, finally returning to Vienna to become a lecturer in the University of that city. In 1899 he became a lecturer in Lwow, and the next year, at twenty-eight, he was promoted to a chair of theoretical physics, thus becoming the youngest professor in Austria. In 1913 he was offered, and accepted, the chair of experimental physics at Cracow, but was evacuated to Vienna in the early part of the First World War. The University of Cracow made him rector when he was invited again in 1917 to the chair of theoretical physics in Vienna, but Smoluchowski died suddenly at the age of forty-five before he could deliver his inaugural address entitled "On the Uniformity of Laws of Nature".

Probability theory played an important part in physics during the forty years following Smoluchowski's premature death, and Smoluchowski can claim to have started and anticipated much of the subsequent development. He, together with and independently of Einstein, elaborated and carried forward the ideas of Maxwell and Boltzmann. One of Smoluchowski's mathematical achievements was the clarification of the ergodic hypothesis of Boltzmann and of its place and meaning in statistical mechanics. He realized the difference between the logical structure of the Maxwell and Boltzmann theories and the statistical mechanics of Gibbs. Though primarily a theoretical physicist, Smoluchowski was also very adept in the design and construction of instruments and an extremely good glass-blower. While at Lwow he carried out a brilliant series of experiments confirming Lord Rayleigh's theory that the blue of the sky was caused by the scattering of light. He paid several visits to Great Britain both for mountaineering in Scotland (one of his great passions), and also on academic business. He was an active member of many scientific societies, in particular the Polish Physical Society, of which he became the first president, and he contributed many papers to scientific periodicals, some collections of which have been published since his death.

MENTAL HEALTH RESEARCH FUND

OFFICIAL figures show that in 1956 there were in England and Wales more than 204,000 hospital beds occupied by patients suffering from mental illness or mental deficiency. This figure can be compared with the 219,000 occupied beds for all other diseases put together. In addition, there were more than 81,000 mental defectives under some sort of supervision provided by the local authority and an unknown number of persons suffering from neuroses which impair their efficiency and happiness. This problem is increasing. In 1949, it led to the formation of the Mental Health Research Fund by a small group of scientists, doctors, and laymen who shared the belief that mental health and mental illness were not receiving that share of attention in research which their importance demands.

The Fund was registered in 1952 and heads of leading research institutions in Great Britain were invited to say in what ways they would wish to use any money that might be available for work in promoting mental health.

A conference at Oxford was then convened to which were invited a wide cross-section of scientists, ranging from anatomists to sociologists, as well as a number of practising psychiatrists and professors of psychiatry. Its terms of reference were to answer the following questions: What are the ignorances which to-day principally hamper understanding of the nature, prevention and cure of mental illness? What advances in research are most likely to remove these and so help to reduce the population of mental hospitals and institutions for delinquents?

The Fund has now defined its main purpose and responsibilities as follows: The establishment of research fellowships in the several fields of mental science; encouraging co-operation between workers in different fields of mental science by arranging conferences; supporting specific lines of investigation by providing technical assistance, expenses or equipment for research workers; and arranging for the exchange of information with workers in other countries by financing attendance at regional and international meetings.

To further these objectives, the Fund proceeded to collect money and make grants on an increasing scale. It was fortunate in receiving grants from the Ford Foundation, the Leverhulme Trust, the Peel Trust and the National Society for Mentally Handicapped Children, as well as valuable support from the general public.

The Fund has now well-established procedures for inviting and assessing applications for support. Every research centre in Great Britain has been informed of the Fund's interest, of the kinds of help it is able to offer, and receives annually its invitation to prospective applicants.

During 1957 the Fund planned and issued invitations to the international conference recently held in Oxford. The theme of this conference was the concept of stress; its main object was to elucidate the variations of this concept as used in psychiatry and to relate them to each other and to the somewhat different concepts of stress which are used in physiology. Information about the Fund may be obtained from 39 Queen Anne Street, London, W.1.

GLACIOLOGICAL OBSERVATIONS ON RUWENZORI

THE Department of Geography of Makerere College in the University College of East Africa has recently distributed a duplicated report* of eighteen quarto pages on the reconnaissance expedition to Mt. Ruwenzori conducted by four members of the College staff during December 28, 1957–January 12, 1958, under the leadership of Mr. F. P. Henderson, lecturer in geology. The object of the expedition was glaciological: it was hoped to make observations on some of the thirty odd glaciers of the mountain which would provide information as to their state during the International Geophysical Year. Oriented photographs were taken from marked sites of the highest peaks, Stanley Ice Plateau, and four or five of the principal glaciers; comparison with photographs taken by earlier expeditions reveals a general and considerable wastage of the Ruwenzori glaciers. In addition, a hut was erected above the snow line, a survey base was marked and measured, and from it the positions of a series of markers on the Elena glacier determined. Only one of several markers placed on this glacier by previous expeditions was discovered, and even this was useless since its original position could not be fixed.

It is concluded by the leader that relatively small expeditions of this type at fairly frequent intervals offer a more promising mode of attack on the problems of this mountain than do more elaborate expeditions widely spaced in time. Accordingly, it was planned to follow up the reconnaissance with a further expedition six months later. On June 23, *The Times* reported that this expedition, again under the leadership of Mr. Henderson, began the ascent of the mountain on June 10, but operations had to be given up on June 18 owing to the illness and death from pneumonia of Mr. William Dickins, lecturer in geography in the Department of Education. During the reconnaissance, one member of the expedition, Dr. Whittow, contracted bronchial trouble and retired from the mountain; and, indeed, high-altitude pneumonia is a well-known phenomenon on Ruwenzori.

The courage of the young men of these two expeditions in planning fairly regularly repeated observations on a mountain with such a notorious weather record and under conditions that allow of little time for acclimatization is wholly to be admired; but the tragic outcome of the second expedition leads one to express the hope that in future their plans may receive, in Government and university circles in Uganda, financial support sufficient to allow them to operate with larger margins and to permit the inclusion of a medically qualified member in the team.

ROLE OF TURBULENT SCATTERING IN LONG-DISTANCE RADIO PROPAGATION AT METRE WAVE-LENGTHS

By F. A. KITCHEN and Dr. M. A. JOHNSON
Royal Naval Scientific Service, London

SOME controversy has recently arisen[1] in regard to the practical confirmation of the theoretical prediction[2,3] that a permanent mechanism of long-distance propagation of short radio waves will arise from scattering by randomly distributed irregularities of refractive index associated with atmospheric turbulence. Some recent experimental results which appear to confirm its presence at metre wave-lengths are now presented.

Following the series of metre-wave experiments recently described[4], further work was carried out by the Admiralty Signal and Radar Establishment in November and December 1957, in the English Channel area, using a ship-borne transmitter against a shore-based receiver near Portsmouth, on a frequency of 203·5 Mc./s. The transmitter and receiver were those used in previous experiments[4], but with the addition of a high-speed continuous recorder of received field-strength, of time constant 0·1 sec., and an automatic signal-level distribution analyser for the determination of the instantaneous amplitude distribution. The latter was operated for 3-min. sampling periods, comprising 1,000 individual signal samplings, for each of which the resolving time was 20 m.sec. The height above sea-level of the receiving aerial was 120 m. and that of the transmitting aerial was 12 m. The latter produced a radiation pattern in the vertical plane in which the lowest lobe was elevated at an angle of about $1\frac{3}{4}$° above the horizon. This has been allowed for in applying the theoretical treatments of the possible propagation mechanisms to the observed results. It is believed that this has no influence on the interpretation of the propagation mechanisms involved.

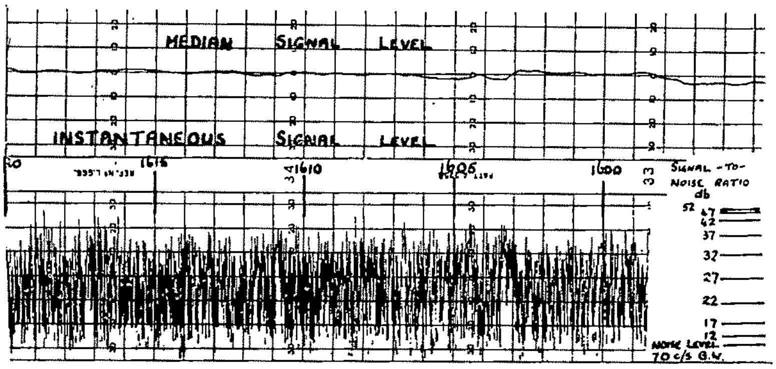

Fig. 1. Long-range propagation measurements, 203·5 Mc./s., December 11, 1957. English Channel area

Field-strength recordings were made for a number of outward runs by the ship, on a true bearing of 245°, for ranges of up to 350 nautical miles. Both the median level and the fading characteristics of the signal were carefully analysed. Further, the instantaneous signal amplitude distributions were obtained from the analyser data by plotting on normal and Rayleigh probability paper. A careful examination was made of the surface and upper-air meteorological data published by the Meteorological Office for the period concerned. Although no upper-air data were available for places nearer the transmission path than Camborne, Cornwall, on each of the particular runs to be discussed the meteorological situation was the same over a wide area surrounding the transmission path, as evidenced by the charts for the various fixed levels and the close similarity of upper-air conditions at Camborne and more distant stations such as Crawley and Valentia.

On each of the three runs made by the ship during the period November 25–29, involving ranges between 110 and 250 nautical miles, the characteristics of the received signal field were very similar, and of a type familiar from previous experiments (ref. 4, type 'B'). The fading was of the 'roller' type: broad flat maxima separated by deep sharp minima, over a range of 20–30 db., and of period 1–5 min. On each run the transmission path lay in the central regions of a persistent anticyclone. It is well known that subsidence normally occurs at upper levels in these conditions, and across the boundary between the subsiding air and the surface layer there will occur both a rapid increase of temperature and a rapid decrease of water-vapour content, giving a thin layer of sharp decrease of radio refractive index. The upper-air meteorological (radio-sonde) data confirm the existence of such a layer, at a level of about 1,500 m., at all the above-mentioned stations. It is difficult to make quantitative estimates of the partial reflexion of the incident wave which will occur at this layer, since the available upper-air data are too coarse to permit its thickness, or the form of the variation of refractive index within it, to be determined. The reflexion coefficient of the layer decreases rapidly if its thickness $t > t_0 = \lambda/4\pi\alpha$, where λ is the radio wave-length and α the angle of incidence on the layer. For the experiment under consideration, the maximum value of this critical thickness t_0 is 15 m. at 110 nautical miles total range, decreasing to 6 m. at 250 miles. However, there is some evidence that inversion layers caused by subsidence in anticyclones can have thicknesses not greatly exceeding these values; this seems reasonable, since under conditions of anticyclonic subsidence wind speeds are small and the temperature lapse-rate is stable, so that turbulence is weak. Although the form of the variation of refractive index within the layer is still unknown, it seems reasonable to assume that the radio transmission was primarily due to partial reflexion from the layer, and this hypothesis is consistent with the fading characteristics of the received signal. The observed median signal-levels were considerably higher (usually 30–50 db. below free space at the shorter ranges, and 50–70 db. below at the longer ranges) than those which scattering theory[3] predicts, particularly since, as already mentioned, the intensity of turbulence was likely to be less than usual. The meteorological data confirm directly that the upper winds were very light and the temperature lapse-rate small. Thus, a contribution from scattering to the received signal would be negligible, by comparison.

However, the results of the run made on December 11–12 were completely different. Throughout this run, which covered the range interval from 140 to 260 nautical miles, the received signal suffered extremely rapid fading (Fig. 1), at a rate of about 30 cycles per minute. The observed median signal-level showed a slow and fairly uniform attenuation with range; its levels at 150 and 250 nautical miles range were respectively about 75 and 90 db. below the free-space values, corresponding to a mean rate of attenuation of 0·15 db./mile. These values are all in good agreement with predictions made from turbulent scattering theory[3]. During the whole of the run the transmission path lay within an air stream which is shown by the upper-air data, and by the development of convective type cloud and showers, to have been unstable, up to at least 7 km. height. Strong turbulence would thus be expected over the most important part of the scattering volume. Further, this instability and turbulence would be likely to preclude the formation of stratified layers, especially of thickness small enough to give appreciable partial reflexion. No inversion layers were apparent in the refractive-index–height distributions constructed from the upper-air data.

Further, the rate of fading observed is in excellent agreement with predictions from scattering theory[5], but would be difficult to explain on the hypothesis of a reflexion mechanism. The instantaneous signal amplitude distributions were close to the Rayleigh form which would be expected for a random scattering process, except in certain cases when significant changes of the mean signal-level were shown by the records to occur during the period of sampling. In the latter cases the distribution of signal amplitude tended towards a log normal form, as would be expected. While a Rayleigh-distributed received signal could also be caused by the addition with random phases of a limited number of signal components reflected at discrete inversion layers, as recently suggested[6,7], this is open to the serious objection, already mentioned, that the strong turbulence present on this occasion made the existence of such thin layers extremely unlikely.

It is therefore suggested that all the evidence points to turbulent scattering as the dominant propagation mechanism on this occasion. Further, since, on both theoretical and experimental grounds[3], it seems that turbulence to some degree must almost always be present at all levels in the troposphere, it may be concluded that the scattering mechanism will be similarly permanent. It will, of course, be frequently masked by the stronger mechanism of partial reflexion, but can only be neglected for purposes for which only occasions of unusually strong transmission are of interest.

The work described is published by permission of the Admiralty. We desire to acknowledge the assistance of Messrs. I. J. Richmond and W. L. Hibbens in the preparation of the experimental equipment and in the conduct of the observations.

PROTECTION OF LIVING CELLS AGAINST ACID BY CERTAIN NON-IONIC AND AMPHOTERIC SOAPS

By DR. P. D'ARCY HART, C.B.E., and DR. J. E. LOVELOCK

National Institute for Medical Research, Mill Hill, London, N.W.7

IT is reported that the interior of phagocytic cells is, or can become, acidic[1], but it is undecided how far this property might contribute to the destruction of certain bacteria ingested by them[2]. Tubercle bacilli can survive and multiply within these cells, or be inhibited in growth or destroyed, according to circumstances[3]; this bacterial species is well known to be relatively resistant to acid, though the resistance is far from absolute[4]. Certain non-ionic soaps, namely, certain polyoxyethylene ethers, which are without apparent effect on the multiplication of tubercle bacilli *in vitro*, exercise a strong effect *in vivo*—some suppressing and others enhancing experimental tuberculous infection; their site of action is considered to be within the monocytic phagocytes[5–8]. It was therefore of some interest to examine the effect of these agents on the resistance of tubercle bacilli to acid.

Preliminary experiments provided no simple explanation of the action of the agents on tuberculosis, but they revealed a general phenomenon which forms the subject of this article. The experiments have been extended to include exposure of other bacteria besides *Mycobacterium tuberculosis*, as well as of human red blood-cells, to acid in the presence and absence of various non-ionic soaps and other compounds.

Suspensions of micro-organisms were obtained from cultures on solid nutrient medium. The reaction mixtures contained usually 1 *M* or 0·1 *M* hydrochloric acid (to give a final measured *p*H of 0·6 or 1·2, respectively), or 0·1 *M* citrate buffer (to give *p*H 3·5, 5·0 or 7·0), or no buffer (*p*H 7·0); a non-ionic soap 1·25 per cent w/v; albumin 0·025 per cent; micro-organisms 10^6–10^7/ml.; total volume 4·0 ml. The mixtures were incubated in 25 mm. diameter test-tubes at 37° C. for 3½ hr., with intermittent shaking by hand. After neutralization, viable counts were made on nutrient medium from 0·02 ml. drops of suitable dilutions. Human red blood-cells were suspended in 0·13 *M* sodium chloride containing 0·03 *M* acetate buffer at a final *p*H of 3·5 and upwards; and the extent of hæmolysis during 3 min., in the presence or absence of the test substance, was noted.

Table 1 shows tests of the effect of non-ionic soaps and other substances, including the phospholipid lecithin, against the lethal action of acid solutions on *N. tuberculosis*. Somewhat surprisingly, all the non-ionic soaps tested (including saponin and polypropylene glycol) are able to protect the bacilli against acid. Even more interesting is the observation that the amphoteric soap lecithin acts similarly. Soaps able to suppress experimental tuberculosis ('Triton *WR*1339') are just as effective as those that are pro-tuberculous (*HOC*-60). Other molecules of similar size but possessing no soap-like activity, for example, polyethylene glycol, sucrose and suramin, were unable to protect.

The protective action of the soaps was next tested with another species of *Mycobacterium*, with three other species of bacteria normally less resistant to acid, and with human red cells. Table 2 shows that the killing of the various bacterial species by acid is also impeded by a typical member of the soaps, though at a different *p*H from that with *M. tuberculosis*. The hæmolysis of red cells by acid is considerably delayed in their presence.

Very approximately the effect of the soaps is to increase the concentration of hydrogen ions required for rapid destruction one hundredfold, that is, a shift of 2 *p*H units. The soaps do not appear to confer complete protection against the bactericidal and hæmolytic effects of acid: their action is to reduce considerably the rate at which damage occurs. In this connexion the bacteriostatic action of weakly acid solutions (*p*H 5–6) upon tubercle bacilli is not prevented by the soaps. Under otherwise identical

Table 1. Lethal Action of Acid on Tubercle Bacilli (Strain *H37Rv*) with or without various Non-ionic Soaps, etc.

Substance	Concentration (per cent w/v)	Survivors (viable units/0·02 ml.) after exposure for 3½ hr. at 37° C. at *p*H: 0·6	1·2	3·5	5·0	7·0
Control without soap	—	< 1	1	30	10,000	10,000
'Triton *WR*1339'*	1·25	< 1	6,000	8,000	10,000	10,000
HOC-60 (*GN*/102)*	1·25	< 1	7,000	—	7,000	—
HOC-75 (*GN*/104)*	1·25	—	—	8,000	—	—
Saponin	1·25	< 1	3,000	—	—	10,000
Polypropylene glycol M.W.425	1·25	< 1	1,000	—	—	10,000
Lecithin (egg)	1·0	—	6,000	8,000	—	8,000
Polyethylene glycol M.W.600	1·25	—	< 1	—	—	10,000
Suramin	1–10	—	< 1	—	—	10,000
Sucrose	1–50	—	< 1	—	—	10,000
Glycerol	5–50	—	< 1	—	—	2,000
		Survivors after exposure for 24 hr.				
Control	—	—	< 1	< 1	—	10,000
'*WR*1339'	1·25	—	850	7,000	—	10,000

* 'Triton *WR*1339' is a polyethylene glycol ether of a *p-tert*-octylphenol-formaldehyde linear polymer; *HOC*-60 and *HOC*-75 are polyethylene glycol ethers of a *p-tert*-octylphenol-formaldehyde cyclic tetramer (with average 60 and 75 ethylene oxide units per phenolic group) (ref. 5).

Table 2. Lethal Action of Acid on various Cell Species with or without 'Triton *WR*1339'

Cell species	Survival after exposure* at *p*H: 1·2		3·5		5·0		7·0	
	Control	Soap	Control	Soap	Control	Soap	Control	Soap
Myco. tuberculosis (*H37Rv*)	1	6,000	30	8,000	10,000	10,000	10,000	10,000
Myco. phlei	< 1	< 1	2	75,000	—	—	75,000	75,000
Staph. pyogenes	< 1	1	3	20,000	—	—	100,000	100,000
Esch. coli	< 1	< 1	< 1	< 1	—	—	80,000	80,000
Strep. viridans	< 1	< 1	< 1	< 1	3,000	50,000	50,000	50,000
Human red cells	—	—	0	100	100	100	100	100

* For the bacteria, survival is indicated by the viable units/0·02 ml. remaining after exposure for 3½ hr. at 37° C. For the red cells, survival is indicated by the percentage of intact cells remaining after exposure for 3 min. at room temperature.

conditions to those listed, similar protection of tubercle bacilli against the acids perchloric (0·1 M to give a final *p*H of 1·2) and phosphoric (*p*H 3·5) was observed. No protection by the soaps against the harmful effects of exposure to alkali has been detected.

So far, we have insufficient evidence to offer an explanation of the mechanism of the protective action of these soaps. There exists, however, a parallel between the protective action and their ability to discharge the colour of fluorescein and similar dyes in acid solutions[9], and this may provide a clue towards the understanding of their action. The failure of solutes such as polyethylene glycol and sucrose to protect would suggest that the protective activity of the soaps is not simply a consequence of the osmotic pressure of their solutions, but rather some specific effect connected with their soap-like properties.

If the phenomenon here reported should be associated with a wide variety of living cells, it might find practical application in certain situations where a temporary and limited protection of cells against acidity is required.

We are indebted to Messrs. Bayer Products, Ltd., London, for supplying 'Triton *WR*1339', and to Dr. J. W. Cornforth and Dr. G. A. Nicholls for preparing the two soaps of the *HOC* series.

DISTRIBUTION OF ANTISTREPTOLYSINS IN PROTEIN FRACTIONS

By Dr. L. GORECZKY
Central Laboratory, Polyclinic of MAV, Budapest

THE relation of immune substances to single protein fractions has been the subject of extensive studies. The recognition of the method of paper electrophoresis by Durrum[1], Grassmann and Hannig[2] and Bockemüller and Rebling[3] and the method of immuno-electrophoresis by Grabar *et al.*[4] has opened new roads in this field. Although the investigations were very extensive, no direct determinations have been published, to our knowledge, concerning the distribution of antistreptolysins in the protein fractions. The method I had formerly employed in studies on the combination of bactericidal agents with protein fractions proved to be very suitable for use in the investigations concerned with the combination of antistreptolysins with those fractions[5].

In studies on the antistreptolysins linked to serum proteins the method has been modified in that the agar was dissolved in a veronal buffer of *p*H 7·4, and to this were added 1 per cent fresh, thrice-washed sheep erythrocytes. The paper strips containing the protein moved by electrophoresis were placed on them. After paper strips had been cut up and put in place, a streptolysin-0 standard (generously supplied by the Behringwerke, Marburg) dissolved in sodium thioglycollate buffer and containing 20 units per ml. was applied to the paper. This was done by placing a platinum loop full of streptolysin-0 solution on the paper at intervals of 30–35 min. over a period of 4–5 hr. In the intervals the plates were incubated at 37° C. in an incubator to promote the reaction. The results were read 8–10 hr. after the placing of strips and beginning of streptolysin administration. The areas showing hæmolysis after the removal of the paper strips were observed, distinguishing two grades in hæmolysis : total inhibition, when there was no lysed area under the paper ; and partial inhibition, when both hæmolysed and non-hæmolysed areas were detectable. The other half of the electrophoretized paper served as the control and after staining was studied by densitometry in an Eppendorf photometer. The extinction values were plotted as a curve. The inhibition of hæmolysis was marked at the appropriate site of the curve and thus the effect of antistreptolysin could be determined accurately.

Sera from normal human subjects and rabbits, as well as from patients showing high antistreptolysin titres (M.I. titre, 1 : 1,100 ; T.E. titre, 1 : 720) were used. The electrophoretic curves and the corresponding antistreptolysin effects are shown in Figs. 1, 2, 3 and 4.

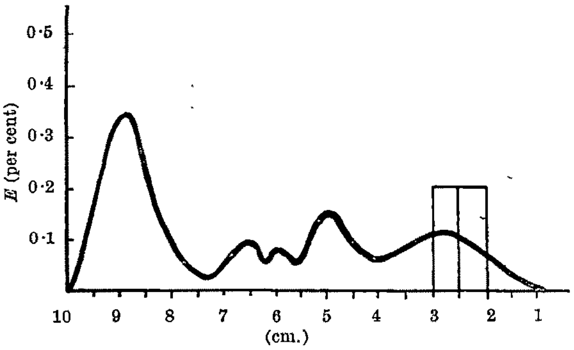

Fig. 1. Normal rabbit serum

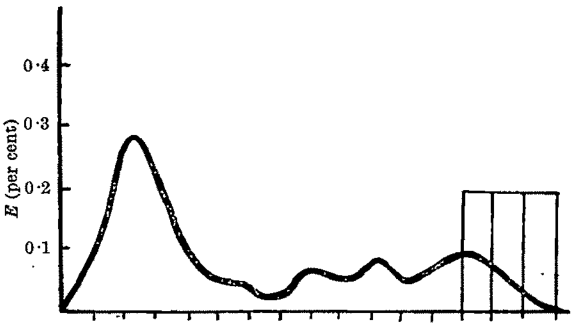

Fig. 2. Normal human serum

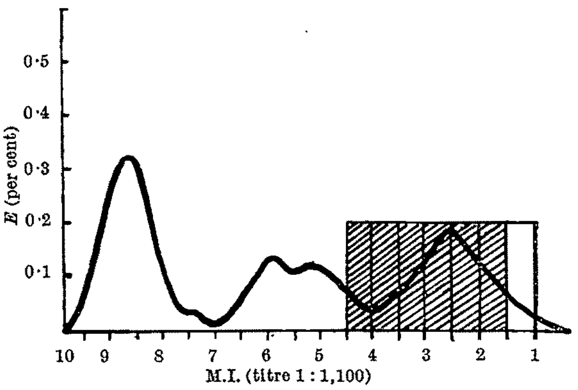

Fig. 3

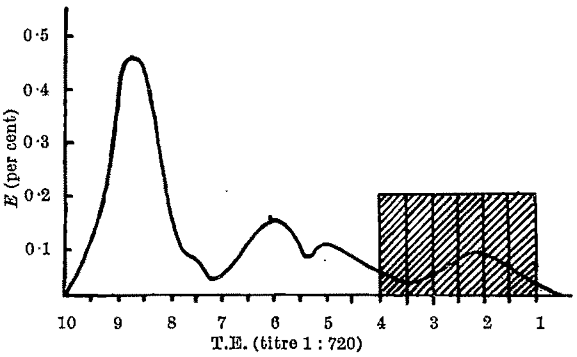

Fig. 4

The columns indicate inhibition of hæmolysis. The shaded columns show total inhibition, the empty ones partial inhibition. It is shown by Fig. 1 that the antistreptolysin effect of normal rabbit serum (titre 1 : 10) is bound exclusively to gamma globulin. The main mass of gamma globulin carries this activity, and this lysin inhibition is absent in the ascending and descending branches of the curve. The effect, however, manifests itself in a partial inhibition only. The normal human sera showing antistreptolysin titres as low as 1 : 100 had the same effect (Fig. 2). Here, too, it was exclusively in the area corresponding to the main mass of gamma globulin that an inhibition of hæmolysis, the manifestation of the antistreptolysin effect, was observable. Here, too, inhibition was only partial.

In contrast with this, the high-titre human sera from patients suffering from streptococcal infection behaved quite differently. First of all, the effect was more intense, in so far as here inhibition proved to be complete. Another remarkable finding was that inhibition could be observed also outside the main mass of gamma globulin, in the areas containing a very low concentration of protein migrating faster than gamma globulin. This area of the electrophoretic curve is what is called the area of the fraction *T*. In this area, too, the effect was substantially more marked than in the case of normal sera. A comparison of the curves for the two pathological sera shows a remarkable difference in the gamma globulin-level between the two sera. Although this was very marked, the two sera did not differ substantially in antistreptolysin titre or in the results concerning the fractions studied (Figs. 3 and 4).

These investigations appear to prove beyond doubt that the immune bodies, at least so far as the antistreptolysins are concerned, differ from the normal gamma globulins. Although no data are available as to their other physical properties, it appears to be unquestionable that these immune bodies migrate at a faster rate than the main mass of gamma globulin. This kind of gamma globulin does not make the immunological significance of gamma globulins questionable, but its existence seems to confirm those experiments in which the immune bodies have been found to be linked not exclusively to gamma globulin[6–8].

Rantz, Rendall and Rantz[9], Imperato[10] and others have reported that a close correlation exists between the level of gamma globulin in serum and the antistreptolysin titre of serum in diseased adults and children. The increase in gamma globulin in such patients can be ascribed to the inflammatory phenomena associated with streptococcal infection and the secondary tissue destruction, rather than to the antistreptolytic activity of sera in such patients. The two curves of the patients offer a strong confirmation of this view, in so far as the immunoantistreptolysins act not only in the area of the gamma globulin but also beyond the main mass of gamma globulin, in the initial part of beta globulin. Considering the amount of serum applied to the paper and the dissociation resulting from migration, it is obvious that only traces of protein can be involved in the effect. This will be even more conspicuous if we take into account also the protein concentration of the interspace between gamma and beta globulin. If we assess planimetrically and by computation the amount of protein contained in the active area on the basis of the quantity of serum applied to the paper (10 mm.^{3}), it will be found that the protein in the interspace between the two fractions corresponds to 1·8 gamma total protein in the case of M.I. and to 0·7 gamma in the case of T.E. This shows clearly how highly active these substances are. Such a high activity is common to the immune reactions in general.

Thus, the experiments with streptolysins have proved beyond doubt that the normal antistreptolysins are different from the immune antistreptolysins, as manifested particularly in a difference in the rate of migration. On the other hand, such minute amounts of protein may suffice to produce a manifest immune effect as cannot be demonstrated in many a case by the highly sensitive reactions, either.

The antistreptolysin studies showed that the antistreptolysin effect of normal human and rabbit sera corresponded to the main mass of gamma globulin. On the other hand, high-titre sera from patients had a very marked effect not only in the area of the main mass of gamma globulin, but also in that between gamma and beta globulin. This evidence suggests that there are apparently two kinds of antistreptolysin, one of which migrates definitely linked to gamma globulin. This occurs in normal sera. The other is an immune body migrating with, and also faster than, the main mass of gamma globulin. This occurs in pathological sera as a result of immunization. The high activity of the substance is shown by the fact that the effect develops also in the presence of very small amounts of protein, as small as 1·8 and 0·7 gamma.

SPATIAL SUMMATION FOR HEAT-PAIN

By Prof. K. R. L. HALL

Department of Psychology, University of Cape Town

THE experiments of Hardy, Wolff, and Goodell[1], using the radiant-heat technique of focused stimulation, and varying the size of skin surface area exposed to stimulation, showed no threshold variation for pain relative to size of skin area within a range from 0·95 to 28 cm^2. Warmth thresholds were, however, shown to increase more than 200-fold as the area of skin stimulated was diminished from 200 to 0·2 cm^2. The authors therefore concluded that the only cutaneous sensation which does not possess this property is pain, thus distinguishing pain functionally from other sensations, and lending support to their thesis that pain is a sensory modality subserved by a special neural equipment.

Weddell and his associates[2–3], in supporting a 'pattern' theory of non-specific representation in cutaneous sensibility, have put forward two reasons why the evidence refuting spatial summation for pain is not conclusive: (1) Breig[4] is said to have demonstrated spatial summation for the pain caused by drawing a pin across the skin; (2) it has been shown, using a dolorimeter constructed in a manner similar to that of Hardy *et al.*, that there is a 50 per cent fall-off in the intensity of radiation from the centre to the periphery of a 9·6 cm.^{2} area, due to the construction of the filament of the lamp used as the source of radiant energy. Thus a cone of radiant heat is applied to the skin area, so that the heat is not uniformly disposed.

The question, therefore, of whether or not it is possible to demonstrate spatial summation for pain may have some crucial bearing on two major theories of sensibility to cutaneous pain.

In the present study, it was decided to use a water-heating system so as to avoid the technical flaw of the radiant-heat technique. This system consisted of two 4-gallon drums filled with water. The water of one drum was maintained at boiling point throughout the experimental sessions by two immersion-heater elements, the drum being encased with heat-insulating material. The other drum was filled with cold tap-water. A rubber tube was connected to an outlet from the lower part of each drum, the flow of water being regulated by a tap. The outflow of boiling and of cold water then merged together in a common pipe to a glass connecting tube at the open base of which a circular disk of brass shim, three-thousandths of an inch thick, was securely fixed with heat-resistant glue. A centigrade thermometer was set into the top of the glass connecting tube, standing perpendicular to the horizontal circular disk and with the tip of the mercury bowl almost in contact with it, the rest of the bowl being completely immersed in the hot water. The continuous merging flow of water from the two drums was regulated by the taps until the desired reading on the thermometer was steady.

For the purpose of this experiment, two sizes of circular metal disk were fitted to otherwise identical glass connecting tubes, the one being of 1 cm. and the other of 2 cm. diameter. These disks served as the heat-stimulus contacts for placing on the skin of the volar surface of the subject's left forearm.

Eight adult subjects took part in the experiment, none having prior knowledge of its specific purpose. Each subject was tested on four separate sessions of 45 min., each session being divided into two half-sessions, during one of which the 1 cm. contact was used, and during the other the 2 cm. contact. The order of presentation of the 1 and the 2 cm. contacts was alternated, so that, on sessions one and three, four subjects received the 1 cm. contact stimuli first, and the 2 cm., after a 5-min. interval, during the second half-session; on sessions two and four these subjects received the 2 cm. first and the 1 cm. after the interval. The order of presentation was reversed for the other four subjects. This alternation was intended as a procedural control for any possible serial effect.

The subject was blindfolded before entering the experimental room, so that he could receive no cues from viewing the apparatus. He was instructed to report simply the quality and intensity of the sensation that he experienced during the 3 sec. of exposure of a heated metal contact on his skin. He was given no clue that the metal contacts would differ in size, and he was asked to try to grade the sensations in terms of warmth, heat, pain or no pain, and to retain, as best he could, a consistency in his judgments throughout all the experimental sessions.

The metal contact, attached to a lever, was automatically lowered on to the skin for the 3 sec. exposure period by means of a timing device operating an electromagnet and armature. Until just prior to the 3 sec. period, the contact was kept at a distance of 8 in. above the subject's forearm. It was then lowered to 3 mm. above the skin, a cardboard screen of that thickness being placed between the contact and the skin. This screen was withdrawn immediately prior to the automatic lowering of the contact, which thus fell with a light pressure on the skin, remained there for 3 sec., and at the end was jerked 3 mm. away from the skin and then a further 8 in. above. The minimum interval between successive exposures was 75 sec., and the skin surface area exposed was varied over a distance of 10 cm. longitudinally and 4 cm. laterally. Between 6 and 10 stimuli of varying heat-intensities were applied at each contact-size, and an interval of 5 min. was allowed between the half-sessions, ostensibly as a 'rest' period for the subject during which he went to an adjoining room but in fact to enable the contact-size to be changed. Each subject thus received a total of about 30 heat-stimuli at each contact-size.

The procedure used to arrive at an appropriate narrow range of heat-intensities at, just above, and below the subject's pain threshold was to begin each half-session with a stimulus estimated to fall 2–3° C. below pain threshold. If the sensation reported was of warmth or heat, with no pain, the intensity was increased by steps until pain was first reported. Then stimuli were presented which were close to this 'standard', and an occasional 'check' stimulus at expected 'warmth' intensities only were interspersed to test the reliability of the reporting. It immediately became clear, however, that the intensities required to elicit pain at the 1 cm. size were likely to be several degrees higher than for 2 cm. Skin temperature was continuously recorded from a thermistor placed on the volar surface of the right forearm, but no significant changes were observed in any subjects as between the 1 and 2 cm. test sessions, and there was very little intra-individual variation once the 'steady' level had been reached. Thus differences in skin temperature do not account for the results reported below.

The present stimulation technique was so arranged that the metal contact fell with a light pressure of identical *total* weight for the 1 and 2 cm. sizes. It was thus possible that the difference in pressure per unit area might affect the subjects' reports. For three of the eight subjects, therefore, the 1 cm. contact was fitted with a 'Perspex' ring, making the total contact area on the skin identical to that of the 2 cm. disc. The results obtained with this variation were so closely similar to those obtained on the other five subjects that they have been grouped with these. By placing thermocouples on the contact side of the metal and on the 'Perspex' ring it was found that the latter heated up to a maximum of 36° C. when the metal contact had been maintained for 20 minutes at 50° C.

With this technique and procedure, the results demonstrate consistently and highly significantly

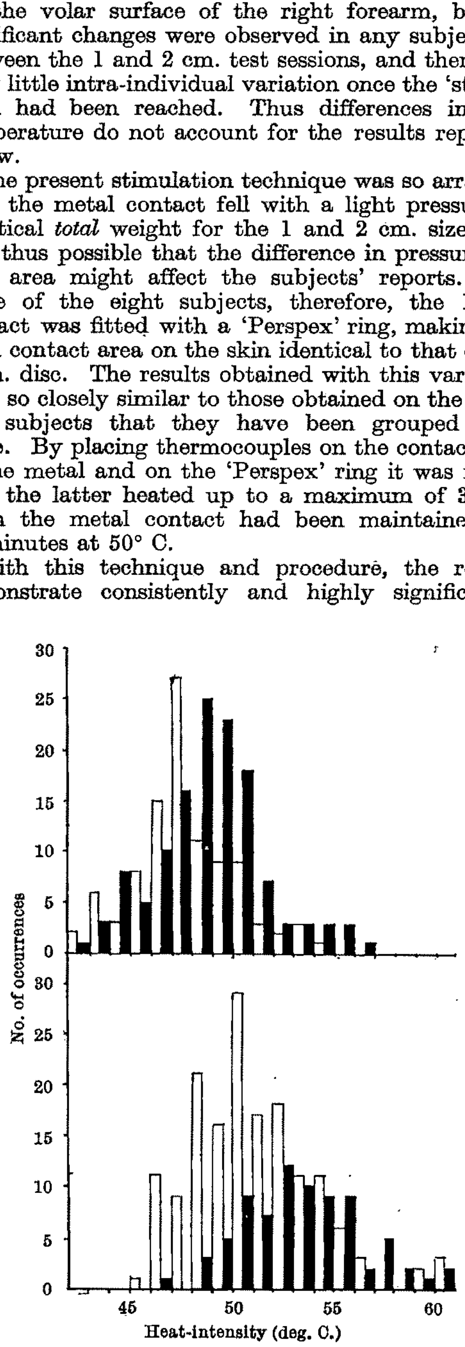

Fig. 1. Histograms showing frequency of occurrence of pain reports (black columns) and no-pain reports (unshaded columns) at various heat-intensities with 2 cm. (upper diagram) and 1 cm. (lower diagram) disks

Coastal and Submarine Morphology

ANDRÉ GUILCHER
Professor of Oceanography at the Sorbonne, Paris

A translation, by R. H. W. Kneese and B. W. Sparkes of Cambridge University, from a French text which appeared in 1954, and to which a number of improvements have been made by the author, so that it is really a new book. Professor Guilcher has an international reputation for his studies in this subject, and many of the examples in the book are drawn from the coast of the British Isles where he has done a great deal of his work. *Illustrated.* 30*s.*

The Ecology of Invasions by Animals and Plants

CHARLES S. ELTON
Director of the Bureau of Animal Populations, University of Oxford

The science of ecology is largely concerned with plant and animal populations, their balance and the changes in them. This book offers an orderly explanation of these changes, and some ideas for the improvement of control. *Illustrated.* 30*s.*

Symposium on Protein Structure

Edited by ALBERT NEUBERGER, F.R.S.

Papers given at an international symposium in which most of the distinguished protein chemists of the world took part. The book offers an unusually topical and comprehensive account of the main branches (with the exception of some of the purely physical chemical aspects) of protein chemistry. *Illustrated.* 45*s.*

The Faraday Society

A GENERAL DISCUSSION

on

ENERGY TRANSFER WITH SPECIAL REFERENCE TO BIOLOGICAL SYSTEMS

will be held at Nottingham University in April, 1959.

The Discussion will be divided into two main sections:

I. Modes of energy transfer from excited and unstable ionized states, to include radiative and radiationless transfer, both intramolecular and intermolecular.
II. Energy migration in organised biological systems, to include semi-conduction, energy transfer in chloroplast, retinal pigments, migration of redox state and transfer of phosphate bond energy.

Anyone wishing to contribute a paper should write to the Secretary, enclosing a brief summary.

The Faraday Society, 6 Gray's Inn Square,
London, W.C.1.

The Faraday Society

A GENERAL DISCUSSION

on

IONS OF THE TRANSITION ELEMENTS

will be held in Dublin from the 9–11th September, 1958, at the joint invitation of Trinity College (University of Dublin) and University College (National University of Ireland).

The Discussion will be divided into two main sections:

I. Optical and Magnetic Properties.
II. Energetics of Complexes.

It is proposed to exclude rare earth and trans-uranium elements and to concentrate on those aspects where the physical and chemical aspects of the subject come together.

Programme and full details obtainable from:

The Faraday Society, 6 Gray's Inn Square,
London, W.C.1.

that there is a spatial summation for heat-pain. The reports made by the eight subjects for the 1 and 2 cm. contacts are summarized in the histograms of Fig. 1, the black columns representing the frequency of reports of pain at the various heat-intensities used, the unshaded columns that of the reports of warmth or heat with no pain.

It will be seen that the frequency of pain-reports over the same range of heat-intensities is considerably greater for the 2 cm. application. Thus if we compare these frequencies over the range from 45·0° C. to 51·9° C., we find pain reported 104 times out of 186 observations (56 per cent) for 2 cm. and only 25 times out of 129 observations (20 per cent) for 1 cm. The χ^2 value of this comparison (42·1) corresponds to $P \leqslant 0{\cdot}001$.

The consistency of the difference is further emphasized by the fact that seven of the eight subjects reported pain at a lower heat-intensity for the 2 cm. contact on each of their four experimental sessions, the eighth subject once only reporting pain at slightly higher intensity for this contact than for 1 cm. Thus, on 31 out of 32 sessions the threshold for pain was lower with the 2 cm. than with the 1 cm. contact. The mean difference between the 1 cm. and 2 cm. pain thresholds for all the sessions was − 5·0 deg. C.

It would seem, therefore, that spatial summation is as clearly demonstrable for cutaneous heat-pain sensation as it is for other cutaneous sensations, so that in this respect pain can no longer be functionally distinguished from these other sensations. It remains, however, to show the spatial limits within which summation takes place and the exact relationship between heat-intensity and size of area stimulated in this way. It will be necessary also to inquire further into the perceptual aspects of spatial summation, for it is of some interest to record that none of the eight subjects at any time reported awareness of a size-difference between the contacts.

I wish to thank Mr. J. G. Taylor for his suggestions on the apparatus used in this study and Mr. P. Humphris for his careful attention to and skill in dealing with the technical aspects of the research. I am indebted to the Staff Research Fund of the University of Cape Town for a grant towards the cost of the apparatus.

ROLE OF ROOT INJURY IN PANAMA DISEASE INFECTIONS

By Dr. LUIS SEQUEIRA, Dr. TAYLOR A. STEEVES, MARGARET W. STEEVES and Dr. JOSEPH M. RIEDHART

United Fruit Co., Division of Tropical Research, Coto Station, Costa Rica

THE *Fusarium* wilt of bananas, commonly called Panama disease, remains one of the major obstacles to be overcome in the cultivation of Gros Michel bananas in the western hemisphere. Although extensive investigations of this malady and its causal agent, *Fusarium oxysporum* f. *cubense* (E. F. Smith) Snyder and Hansen, have been carried out during the past half century, there is no general agreement as to the means by which the fungus enters the host plant. It is generally acknowledged[1] that infection does not occur by way of the pseudostem or the leaves, but it has been suggested[2] that penetration may occur through cuts on the rhizome or true stem. Wardlaw[3], however, has reported that under favourable soil conditions histological reactions within the rhizome tissues prevent significant penetration of the disease organism. In an early description of Panama disease, Brandes[2] presented evidence for penetration through intact tissues of main or primary roots close to the root apex. Wardlaw was unable to obtain root penetration in healthy active roots, but reported infections both of main roots and of lateral rootlets under conditions unfavourable for their active growth[4] or following plasmolysis[5]. He also observed fungus penetration into young main roots decapitated near their tips and studied invasion of trimmed root bases which in some cases led to actual rhizome infections. He considered trimmed root bases, together with insect injuries of the rhizome, as the major sites of infection. More recently Rishbeth[6] described healthy lateral rootlets as the major infection site, and indicated that penetration does not occur directly through the main roots in any circumstances. Finally, Stover[7] has reported that, in agreement with Rishbeth's findings, invasion in Nature occurs at or near the root-cap of lateral rootlets.

In view of the disagreement in the literature, this problem was re-examined here. As experimental material, young Gros Michel banana plants, grown from small seed pieces, were used. Plants to be studied were grown in large clay pots of soil or vermiculite, in root observation boxes having one glass side which was removable, or in a moist chamber. Experimental inoculations were made with three morphologically distinct isolates of *F. oxysporum* f. *cubense* which proved to be equally pathogenic under the conditions used. In some experiments an agar suspension of spores was applied to the roots, and in other cases spores were incorporated into freshly sterilized soil in which the plants were afterwards grown. Infections were studied only in the roots and were identified by the characteristic red or yellow discoloration of the vascular tissue. In all experiments, the pathogen was re-isolated from tissues suspected of infection. Histological studies were made on fresh material by means of hand sections, with supplementary evidence provided by serial sections prepared according to standard procedures[8].

An initial attempt was made to study possible direct infection of main roots as described by Brandes[2]. A heavy spore suspension in molten agar was applied to root surfaces both at the growing tip and in mature regions. No penetration was observed,

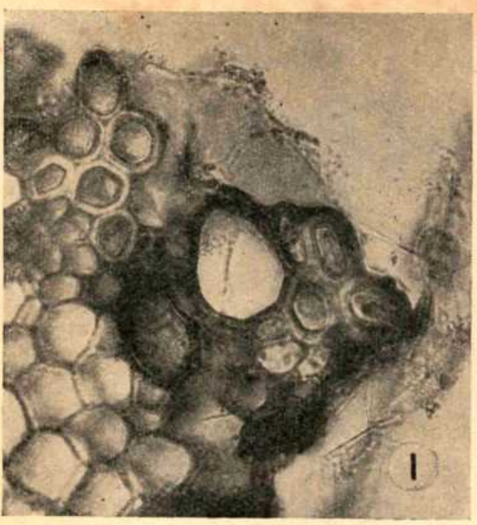

Fig. 1. Transverse section of a main root of a banana plant cut in the region of a deep lateral gash. A suspension of *Fusarium* spores in agar had been applied two days earlier. Hyphæ are visible both inside and outside the exposed vessel (× 275)

and the pathogen gave no evidence, in these experiments, of an ability to attack living cells of the main root. The roots used were growing in sterilized soil and were apparently healthy and vigorous. When, however, injuries were made prior to inoculation, the results were quite different. If in the region of mature tissues a deep lateral gash was made with a scalpel in such a way as to cut the vascular tissues and expose the xylem vessels, rapid (two days or less) penetration of the pathogen into the vessels was observed (Fig. 1). The same result was obtained whether the injury was treated with a spore suspension or whether the roots were merely growing in artificially infested soil (see Table 1). A similarly rapid penetration resulted from needle punctures or scalpel cuts before inoculation, provided that the vascular tissue was involved in the wound. It is interesting to note that shallow gashes or other wounds which did not reach the vascular tissue did not permit entry of the fungus. A layer of cortical parenchyma only two or three cells in thickness appeared to prevent infection completely, further substantiating the earlier observations of the inability of the fungus to attack living cells of the main root. Severing the main root in the mature region also provided a favourable site of infection, but the results were somewhat less consistent (Table 1). When lateral gashes or decapitations were performed in the immature regions of the root near the growing tip no penetration was observed. It remains to be determined whether rapid wound healing in this region is responsible for the failure or if some other factor, such as inability of the disease organism to penetrate immature vessels, is involved.

Table 1. PENETRATION OF WOUNDED MAIN ROOTS OF BANANA

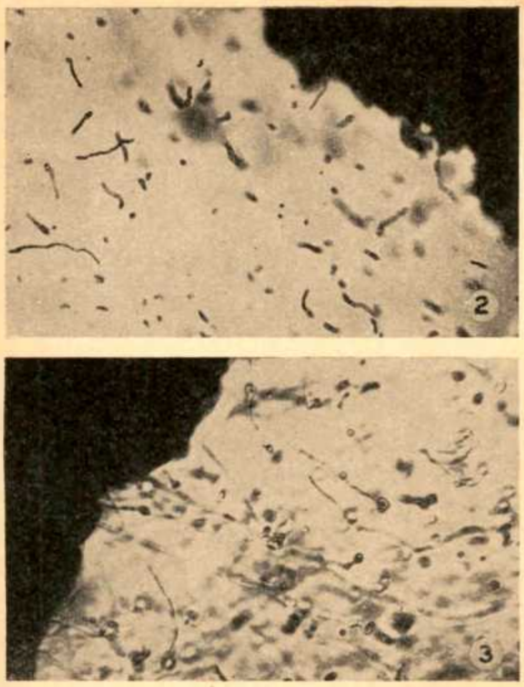
Type of wound	No. of roots Inoculated	No. of roots Penetrated
Spores in agar. Sterile vermiculite		
Deep lateral gash	9	9
Shallow lateral gash	3	0
Needle punctures	5	5
Knife cuts	5	5
Spores in agar. Sterile soil		
Decapitation near tip	7	0
Decapitation mature region	7	5
Deep lateral gash	9	9
Shallow lateral gash	3	1*
Deep gash near tip	2	0
Artificially infested soil		
Decapitation near tip	9	0
Decapitation mature region	8	3
Deep lateral gash	9	9
Shallow lateral gash	3	0

* Histological examination subsequent to the termination of the experiment showed a slight injury to the vascular system.

The importance of injury in *Fusarium* infections of main roots suggested that a similar condition might well prevail in lateral rootlets, in spite of earlier reports to the contrary. In preliminary experiments it has not been possible to establish with certainty the importance of injury primarily because the extreme fragility of lateral rootlets makes it almost impossible to eliminate injury in any experimental treatment. Experiments were conducted by applying a spore suspension in agar to rootlets, on a restricted region of a main root, or by studying roots growing in infested soil. Injury was produced artificially by clipping rootlets with scissors about midway along their length.

When spore suspensions were applied to supposedly unwounded rootlets, in many cases infection of the main root resulted in the region to which these rootlets were attached. Since, in general, there were no injuries of the main roots in these regions, it was concluded that penetration by way of rootlets does occur. However, as has been pointed out, it was not possible in these experiments to eliminate the factor of rootlet injury. It was quite evident that penetration was of much more frequent occurrence if the rootlets were deliberately injured by clipping. On the other hand, even such deliberate injury did not guarantee infection. The most striking observations were those made on plants growing in infested soil in root observation boxes. After large main roots bearing numerous laterals had developed adjacent to the glass side, this was removed with very little disturbance to the roots and on certain ones rootlets were clipped on one side only. The glass side was then replaced. Three weeks later the roots were removed and examined. Characteristic discolorations caused by the fungus were found only in those main roots the rootlets of which had been clipped and only on the side of the root to which these rootlets were attached. This evidence, while it clearly does not rule out penetration by way of intact rootlets, does suggest that injury may be an important factor in rootlet invasion. An extensive histological study of inoculated rootlets, both wounded and intact, did not reveal the presence of *Fusarium* hyphæ. This is in agreement with the observation of Rishbeth[6] that hyphæ are seen in rootlets only with great difficulty, and it suggests that although hyphæ probably are present in some cases, they do not ramify extensively through rootlet tissue.

In examining wounded main roots to which an agar spore suspension had been applied, a marked difference in extent of germination was noted between spores in proximity to the wounded surface and those in contact with an intact surface. There appeared to be a consistent stimulation of spore germination in the vicinity of a wounded root surface (Figs. 2 and 3). In order to verify the existence of such a stimulatory effect, a suspension of spores in agar was applied to wounded and intact main root surfaces on plants in a moist chamber. Control samples of the suspension were placed on glass slides in Petri dishes in the same laboratory room. When



Figs. 2 and 3. (2) Limited germination in the spore–agar inoculum after three days in contact with an unwounded root surface (right) (× c. 330). (3) Extensive germination and mycelial development in the same inoculum shown in Fig. 3 after two days in contact with a lateral gash on the main root. Note marked tropic response towards the wounded surface (left) (× c. 330)

spores from the three treatments were examined after twenty-four hours, it was apparent that germination had been markedly stimulated in proximity to the wound in comparison both with the control and with the intact root surface. Moreover, there was a definite inhibition of spore germination, as compared with the control, by the intact root surface. This observation is in striking contrast to the recent report of Jackson[9] that germination of spores of *Fusarium solani* was stimulated by the presence of intact seedling roots. A chromatographic analysis of the materials diffusing from injured banana roots revealed that the factors stimulating *Fusarium* germination and multiplication are amino-acids and, of these, glutamine appears to be the most important.

The observations reported in this article strongly suggest certain conclusions which may be of importance in future studies of Panama disease. In the first place, the current tendency to disregard the main roots as important infection sites must be re-examined in the light of clear evidence of the penetration of these organs when they have been injured. Secondly, the role of injury in Panama disease infections must be considered in all future investigations, not only as a condition making penetration possible but also as a source of influences which bring about a stimulation of the germination of *Fusarium* spores, thereby increasing the likelihood of successful penetration. In studies now in progress it is hoped to provide a critical evaluation of the importance of injury in the penetration of lateral rootlets by the fungus. Moreover, it will be necessary to determine the applicability of the observations reported here to banana plants growing in different circumstances and particularly under field conditions. The frequent occurrence of serious wounds in banana roots in the field, not only on lateral rootlets but on main roots as well, is certainly compatible with the concept of injury as a major factor in Panama disease infections.

THE REARRANGEMENT OF EPINEPHRINE

By Dr. J. H. FELLMAN

Division of Neurology, University of Oregon Medical School, Portland 1, Oregon

THE study of the enzymatic alteration of a metabolite logically starts from the knowledge of the nature of its electronic configuration and an appreciation of the chemical susceptibilities of the molecule. Such information provides a rational avenue for an investigation into the metabolic pathway. When this approach was applied in a study of the metabolic degradation of the catechol amines, an interesting possibility for a channel of metabolism emerged. I wish to report a rearrangement of epinephrine and norepinephrine of the pinacol–pinacolone type, leading to the formation of 3,4-dihydroxyphenylacetaldehyde. Since this aldehyde is a direct intermediate of 3,4-dihydroxyphenylacetic acid, one of the metabolites which has been reported to be a product from the incubation of norepinephrine with liver slices[1], this rearrangement may represent a chemical model for a further biochemical pathway of catechol amines.

Rearrangement of epinephrine and norepinephrine to 3,4-*dihydroxyphenylacetaldehyde.* To 200 mgm. of epinephrine or norepinephrine was added 3 ml. of 85 per cent phosphoric acid. (The reaction also proceeds with other strong acids such as 20 per cent hydrochloric acid.) The reaction mixture was heated rapidly to 125° C. for no more than 20 sec. and poured into 30 ml. of water. This solution was extracted twice with 10 ml. of ethyl acetate and the extract was washed with 5 ml. of water. The ethyl acetate of the extract was removed by evaporation with a stream of nitrogen. The residue (62 mgm.) was a clear, highly viscous oil which did not crystallize in the cold. This material was used for making derivatives.

The 2,4-dinitrophenylhydrazone of 3,4-dihydroxyphenylacetaldehyde was recrystallized from ethanol (melting point found, 169–70° C.; melting point lit. (ref. 2), 169–70° C.; analysis for $C_{14}H_{12}N_4O_6$ requires C, 50·60 per cent; H, 3·61 per cent; N, 16·86 per

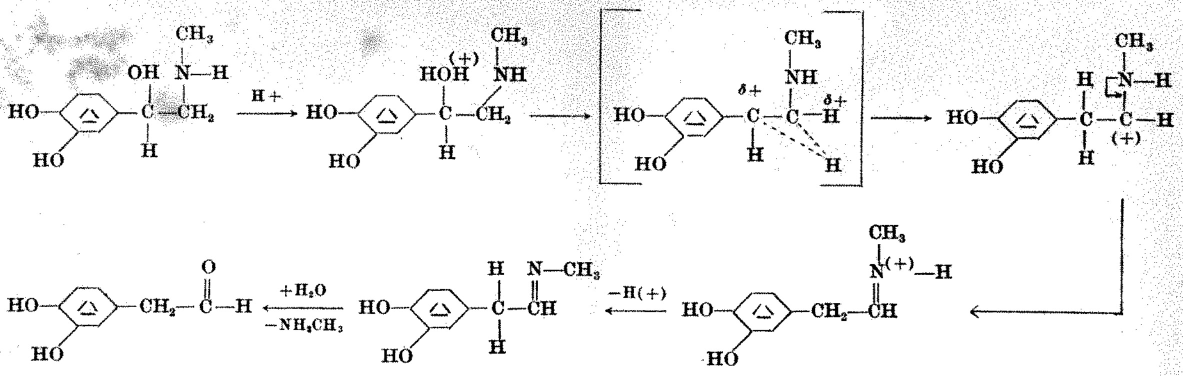

Fig. 1

cent: found C, 50·58 per cent; H, 3·76 per cent; N, 16·60 per cent.). The semicarbazone of 3,4-dihydroxyphenylacetaldehyde was recrystallized from ethanol/water (melting point found, 198–200° C.; melting point lit. (ref. 2), 199–200° C.).

Properties of 3,4-*dihydroxyphenylacetaldehyde.* This aldehyde appears to be quite stable when stored at − 15° C. It is very unstable in alkaline solution, rapidly turning brown then black to form complex polymeric products. It can be chromatographed on Whatman No. 1 paper in acid solvent, *n*-butanol/1·0 *N* hydrochloric acid, having an ascending R_F of 0·70. The catechol aldehyde exhibits the expected absorption peak in the ultra-violet at 280μ.

The effect of 3,4-dihydroxyphenylacetaldehyde on the isolated rabbit ileum and on the isolated uterus of the rat was determined using the methods described by Burn[3]. It was about 500–1,000 times less active than epinephrine in these systems. With 0·025–0·1 mgm. of the aldehyde per ml., marked relaxation of the isolated ileum and an inhibition of the contraction of the isolated rat uterus induced by acetylcholine was observed.

Holtz *et al.*[4] claimed that when urine, shown to contain oxytyramine, was incubated with tissue in the presence of oxygen a material was produced which had a depressor effect on blood pressure. They assumed that the depressor agent was 3,4-dihydroxyphenylacetaldehyde.

The material, prepared as described above, was tested for its effect on the blood pressure of a dog. The mean arterial blood pressure was determined with a mercury manometer connected to the cannulated femoral artery of animals anæsthetized with 'Nembutal'. Injections of as much as 24 mgm. 3,4-dihydroxyphenylacetaldehyde per 10 kgm. body-weight of the dog had no effect whatever on the dog's blood pressure.

From my observations on the lability of this material it is very unlikely that Holtz *et al.*[4] could have obtained it directly from incubation mixtures under the conditions which they described.

Rearrangement of ephedrine to phenylacetone. 100 mgm. of ephedrine sulphate was treated with 3 ml. of 85 per cent phosphoric acid at 130° C. for 2 min. The sweet odour of phenylacetone was readily apparent. The reaction mixture was poured into 30 ml. of 0·1 per cent 2,4-dinitrophenylhydrazine in 2 *N* hydrochloric acid. The derivative begins to form immediately. The precipitated hydrazone of phenylacetone was recrystallized from ethanol (melting point, 152–53° C. uncorrected; melting point lit. (ref. 5), 152–53° C.).

In 1860, Fittig[6] discovered that when the 1,2-glycol, pinacol, was treated with sulphuric acid, it underwent rearrangement to a ketone, pinacolone. Since that time a large number of substituted 1,2-glycols have been shown to undergo this conversion and reactions of this general type have become known as the 'pinacol–pinacolone rearrangement'.

The mechanism of this rearrangement has been extensively investigated and much has been learned about the aptitude of the various groups to migrate, the nature of the intermediate transition state of the molecule, and the effect of the character of substituent groups on the migrating species.

From the product of the acid-catalysed rearrangement of epinephrine, of norepinephrine, or of ephedrine, one may deduce that a similar mechanism will account for the carbonyl compounds formed.

In this case, as in the general pinacol–pinacolone rearrangement, a proton is added to the hydroxyl-group, which is thus eliminated as a water molecule, leaving a residual positive charge in the form of a carbonium ion. Simultaneously with its formation, the vicinal hydrogen is attracted, producing a positive charge on the adjacent carbon from which the hydrogen has migrated. This carbonium ion attracts electrons from its electronegative neighbour, the amino-group, to form, with a loss of a proton, the unstable imino-group. Hydrolysis of this group to the carbonyl-group takes place as shown in Fig. 1.

A similar explanation for the rearrangement of D-1,2-diphenyl-2-amino,1-anisyl ethanol has been advanced by McKenzie and Mills[7].

In the case of ephedrine either the hydrogen- or the methyl-group could migrate. Since phenylacetone alone was formed in this reaction it is clear that it was the hydrogen that migrated. This is consistent with the observations of other workers that the migratory aptitude of hydrogen is greater than that of any other group[8].

Formation of Non-Enzymic Hæm

NEILANDS[1] has described the formation of coprohæm from iron and coproporphyrinogen in aqueous solution at physiological *p*H. Since uroporphyrinogen and coproporphyrinogen, rather than the porphyrins themselves, are now believed to be the true intermediates in the biosynthesis of hæm[2,3], it would be tempting to postulate that protoporphyrinogen is the intermediate which reacts *in vivo* with iron to form protohæm. Further to test this hypothesis, we have incubated aqueous solutions of coproporphyrinogen, coproporphyrin and protoporphyrin with ferrous salts under various conditions and have estimated the hæm formed spectrophotometrically as the pyridine hæmochrome.

Coproporphyrinogen ($1–2 \times 10^{-4}$ *M*) after 16 hr. incubation at *p*H 6 and 37° C. in the presence of large excess of ferrous ions ($1–5 \times 10^{-2}$ *M*) formed a small amount of coprohæm: less than 10 per cent when incubated under nitrogen and much less when incubated in air. However, starting from coproporphyrin, we found up to 25 per cent formation of coprohæm on incubation for 16 hr. at 37° C. under nitrogen and up to 12 per cent on incubation in air. At 100° C. in air the yields from both coproporphyrin and coproporphyrinogen were high and approximately the same. The porphyrinogens are readily oxidized to porphyrins by atmospheric oxygen and the coproporphyrinogen solutions always contained some coproporphyrin, even in those experiments in which incubation was carried out under nitrogen. It cannot be excluded that the formation of hæm observed when coproporphyrinogen was incubated with ferrous iron was derived, in fact, from coproporphyrin.

Protoporphyrin incubated with ferrous salts under the same conditions as were used for coproporphyrin was precipitated from solution and gave no detectable protohæm, but when native globin was added in order to solubilize the porphyrin there was an appreciable formation of hæm (up to 10 per cent with about 10^{-4} *M* porphyrin and 10^{-2} *M* ferrous iron). 'Teepol' (sodium alkyl sulphates) was even more effective; it held both the porphyrin and the ferrous iron in solution at all *p*H values in the range of neutrality (Phillips has used various detergents in order to measure the spectra of porphyrin esters in aqueous media; unpublished work). The yields of protohæm varied from 20 to 45 per cent over the *p*H range 5–8.

A high degree of reproducibility was not possible, particularly in the presence of ferrous hydroxide, which was probably oxidized to varying degrees depending upon small differences in the conditions. Nevertheless, we feel that our results demonstrate clearly that porphyrins and ferrous iron combine under conditions of physiological *p*H and temperature.

In a more complete study of this problem at least two points deserve closer examination. We found that in the presence of 'Teepol' the pyridine hæmochrome of the hæm formed from protoporphyrin had an absorption maximum at 550 mμ in place of 557 mμ. We also found difficulty in getting appreciable incorporation at 37° C. (not at 100° C.) of iron into coproporphyrin formed by the autoxidation of coproporphyrinogen, as opposed to incorporation into coproporphyrin added as such.

Goldberg *et al.*[4] have shown that protoporphyrin will serve as a substrate *in vitro* for an enzyme system forming hæm from nucleated erythrocytes. It seems unlikely that protoporphyrin could be reduced to porphyrinogen by a hydrogenase of avian erythrocytes, since even a powerful reducing agent such as dithionite will not bring about this reduction.

Two distinct stages may be observed in the chemical reduction of porphyrins and in the course of re-oxidation. The fully reduced porphyrinogen (hexahydroporphin) is colourless, but an intermediate stage exhibits a yellow colour and a urobilin-like spectrum with a broad absorption maximum in the region of 500 mμ. This may be a dihydro- or tetrahydro-porphin with a dipyrrylmethene-like structure, and it is of interest that addition of dithionite reduced this intermediate to the colourless porphyrinogen (cf. ref. 3). Such reduction might well be accomplished by a reverse reaction of the erythrocyte dehydrogenases and might constitute the mechanism whereby the porphyrinogen intermediates of hæm synthesis are normally prevented from 'escaping' as uro- or copro-porphyrin, porphyrins which can no longer be drawn back into the system of hæm formation. Indeed, it might be wondered whether in pathological conditions associated with production of excess of free porphyrins, for example, porphyria cutanea tarda[5], some derangement had not occurred in these reducing systems.

From our results, and from these considerations, taken in conjunction with the known ease of entry into the porphin macrocycle of divalent ions such as iron, copper and zinc, we suggest that, in the biological formation of hæm, iron reacts with protoporphyrin, not with protoporphyrinogen.

Evidence for the Involvement of Ferrous Iron in the Biosynthesis of δ-Aminolævulic Acid by Chicken Erythrocyte Preparations

DURING an investigation into the mode of action of 5:6-dimethylbenzimidazole as an inhibitor of δ-aminolævulic acid synthesis in particulate preparations of chicken erythrocytes[1], a range of metal ions was examined for effect on the inhibition. The following metals were without any significant effect: cobalt, copper, nickel, magnesium, manganese, lead and ferric iron. Ferrous iron, however, consistently diminished the inhibition; a typical set of results is shown in Table 1. Addition of ferrous sulphate to freshly prepared systems not containing inhibitor produced a depression of synthesis of δ-aminolævulic acid. If, however, the preparation was aged at

Table 1. Effect of Ferrous Sulphate on the Inhibition of Synthesis of δ-Aminolævulic Acid by 5 : 6-Dimethylbenzimidazole

Ascorbic acid (1 m*M*)	140	61	34	37

0–4° C. for periods exceeding 24 hr., then significant stimulations were obtained. Up to periods of 72 hr., the stimulation increased in magnitude with progressive ageing. Table 2 is typical of results obtained in this way.

The implication of these findings appeared to be that ferrous iron is involved at some stage in the synthesis of δ-aminolævulic acid but that, on ageing, it is progressively oxidized to the ferric state, which has been found to be devoid of stimulatory activity. If this hypothesis be correct, addition of a suitable reducing agent to aged preparations would be expected to have the same effect as addition of ferrous salts. That this is in fact the case was verified by use of ascorbic acid. As in the case of ferrous sulphate, no stimulation was obtained with fresh preparations (see Table 2). The depression of synthesis of δ-aminolævulic acid in fresh preparations by ferrous sulphate is reminiscent of the observation that several microorganisms which synthesize porphyrins (via δ-aminolævulic acid) require small amounts of iron but that larger amounts are inhibitory (see, for example, Pappenheimer[2]). That it was not due to the sulphate anion was shown by including controls containing potassium sulphate.

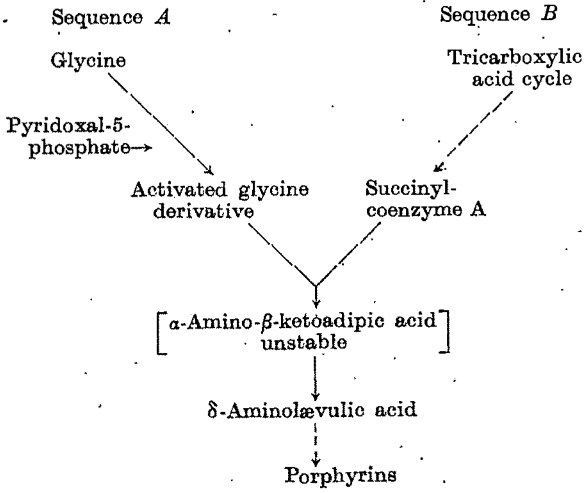
Further evidence that ferrous iron is involved was obtained by demonstrating inhibition of synthesis of δ-aminolævulic acid in the presence of α-α′-dipyridyl, a potent chelating agent for ferrous iron. This inhibition could be reversed by addition of ferric sulphate (Table 3).

Table 3. Inhibition of Synthesis of δ-Aminolævulic Acid by α-α′-Dipyridyl and its Reversal by Ferrous Sulphate

Incubations under standard conditions (ref. 1) with preparation aged for 48 hr. Substrates glycine (30 m*M*) and citrate (30 m*M*)

Additions	δ-Aminolævulic acid (mμ moles)
None	51
α-α′-Dipyridyl (1 m*M*)	41
α-α′-Dipyridyl (1 m*M*) + ferrous sulphate (1 m*M*)	50
Ferrous sulphate (1 m*M*)	80

The current conception of the early stages of porphyrin biosynthesis, of which δ-aminolævulic acid is an intermediate, may be represented as follows:



As 5 : 6-dimethylbenzimidazole inhibits somewhere[1] in sequence *A*, and in view of the relationship of this substance to stimulation by ferrous iron, it would seem likely that ferrous iron exerts its stimulatory capacity in the steps comprising sequence *A*. Preliminary experiments in which production of succinyl-coenzyme A was assayed in control aged systems and in aged systems stimulated with ferrous sulphate confirm this, ferrous iron producing no stimulation but in fact slightly inhibiting sequence *B* (see Table 4).

Table 4. Comparison of the Effects of Ferrous Sulphate on Yield of δ-Aminolævulic Acid and Production of Succinohydroxamic Acid under Comparable Conditions

Incubations conducted under standard conditions (ref. 1) with 48-hr. old preparations. Incubates for estimation of δ-aminolævulic acid contained glycine (30 m*M*) and citrate (30 m*M*). Those for estimation of hydroxamic acid by the method of Lipmann and Tuttle (ref. 7) contained 40 m*M* hydroxylamine but neither glycine nor pyridoxal-5′-phosphate

Additions	Succinohydroxamic acid (mμ moles)	δ-Aminolævulic acid (mμ moles)
None	550	54
Ferrous sulphate	410	99

By analogy with other pyridoxal-5′-phosphate systems, it seems likely that glycine is activated by the formation of Schiff's base with pyridoxal-5′-phosphate (the involvement of the latter in the formation of δ-aminolævulic acid having been demonstrated by Schulman and Richert[3]) and that a metal may be involved in stabilizing the base by chelation. This may well be the site of action of the stimulation by ferrous iron. Evidence has been presented recently by Patwardhan[4] that ferrous iron might be involved in the reaction mechanism of glutamic-oxaloacetic transaminase, another pyridoxal-5′-phosphate system.

That iron is involved in the synthesis of porphyrins has been suggested previously. Duesberg[5], for example, demonstrated decreased porphyrin excretion in patients with iron deficiency. Further, Heilmeyer and Plöttner[6] reported that intravenous injection of ferrous ascorbate leads to synthesis of hæmoglobin in excess of that calculated for complete utilization of the iron supplied. Pappenheimer[2] has shown that synthesis of porphyrin in *Corynebacterium diphtheriae* is stimulated by iron (ferrous sulphate) in concentrations up to 0·1 mgm./l. of culture medium, although concentrations in excess of this are inhibitory. Again, it has been known for many years that iron is required for the synthesis of chlorophyll in plants, although chlorophyll itself does not contain this metal. δ-Aminolævulic acid, however, is an intermediate of this biosynthetic process[8]. Further work on these observations is in progress and will be reported in full elsewhere.

I wish to thank Prof. C. Rimington for his interest and advice and Miss B. Knight for technical assistance during the course of this work, which was carried out during the tenure of an I.C.I. Research Fellowship.

Effect of Copper Deficiency on Synthesis of Hæm

Although copper is essential for the formation of normal hæmoglobin, it has not been demonstrated that this element functions directly in the synthesis of hæm. We have demonstrated an increased synthesis of hæm *in vitro* from glycine labelled with carbon-14, by means of adding inorganic copper to copper-deficient chicken blood.

Cross-bred chicks from a commercial hatchery were rendered deficient in copper in two weeks by feeding the following diet: non-fat milk solids, 55 per cent; glucose-monohydrate, 40 per cent; cotton-seed oil, 2 per cent; glycine, 0·6 per cent; L-arginine monohydrochloride, 0·5 per cent; L-cystine, 0·2 per cent; choline chloride, 0·6 per cent; and sodium chloride, 0·5 per cent. In addition, each 100 gm. of diet contained 2 mgm. of nicotinic acid, 240 I.U. of vitamin A-palmatate, 12·4 mgm. magnesium sulphate, 1·9 mgm. manganese sulphate and the equivalent of 14 mgm. carbonyl iron (General Aniline Works, Grasselli, New Jersey). The iron was fed in the carbonyl form in experiments 1, 2 and 3 and in the chloride form in experiments 4, 5 and 6. The control diets were supplemented with 1·6 mgm. of copper sulphate per 100 gm. of diet. The criteria for deficiency in copper were reduced growth-rate and hæmoglobin concentration.

To determine the effect of a deficiency of copper on synthesis of hæm, 0·1 ml. of a solution of glycine containing 1 μc. methylene-labelled glycine and sufficient non-labelled glycine to yield a final concentration of $1·33 \times 10^{-2}$ *M* was added to either 3 or 5 ml. of heparinized whole blood. In addition, antibiotics[1] and 0·1 ml. of a ferrous sulphate solution were added to yield a final concentration of 2×10^{-4} *M*, as recommended by Dresel and Falk[2]. All samples were incubated at 37·5° C. under an oxygen atmosphere in a Warburg apparatus for 24 hr. Hæm was isolated and recrystallized according to the method of Shemin *et al.*[1], except that strontium chloride was used instead of sodium chloride. A large excess of carrier hæm was added in experiments 2, 3, 4 and 6 but not in experiments 1 and 5. In each experiment blood samples from 4–10 chicks were pooled and incubated either with or without supplemental copper sulphate to a final concentration of $1·6 \times 10^{-5}$ *M*.

Table 1. Effect of Copper on Synthesis of Hæm in Blood Deficient in Copper

Experiment*	Treatment†	Weight gain‡ (gm.)	Hb (gm. per cent)	Specific activity of hæm −Cu	Specific activity of hæm +Cu	Standard error of the mean $S_{\bar{x}}$	Significant level of the copper effect

	Cu-def.	39·9	5·18	3·8	3·6		0

* Results in experiments 1, 2 and 3 are from chicks fed carbonyl iron. Results in experiments 4, 5 and 6 are from chicks fed iron chloride.

† Control diet contained 1·6 mgm. copper sulphate per 100 gm. of diet.

‡ The weight gains in experiment 5 are for four weeks and all others are for two weeks.

The results in Table 1 show that in blood from chicks deficient in copper and fed the diet containing carbonyl iron, synthesis of hæm was reduced, but the addition of copper to this blood consistently increased this synthesis. Blood obtained from chicks deficient in copper and fed iron chloride, however, gave an increased synthesis of hæm in the presence of copper only in experiment 4. With the exception of experiment 3, the addition of copper to the blood from control chicks failed to increase the synthesis of hæm. This exception may possibly be related to the low concentration of hæmoglobin in the control chicks of this experiment.

The results obtained in these experiments demonstrate that copper has a direct function in the synthesis of hæm. From the fact that the copper effect was obtained consistently only when carbonyl iron—a source of iron of low availability—was used in the diet, it appears that a dual copper–iron deficiency may be essential to demonstrate the effect of copper on the *in vitro* synthesis of hæm.

Experiments are in progress to determine the site(s) of copper activity in the synthesis of hæm. Recently, Iodice, Richert and Schulman[3] have demonstrated that δ-aminolævulinic acid dehydrase contains copper and that its activity is reduced in copper-deficiency. It is possible, however, that copper has functions in the synthesis of hæm other than in connexion with this enzyme and the system described here should prove beneficial in elucidating the role of copper in the synthesis of hæm.

We wish to thank Dr. C. H. Hill for providing the chicks used in these experiments and for his aid and advice in the care and feeding of them. This project was partially supported by a grant from the Frasch Foundation.

Effect of Gamma-Radiation on Ferriprotoporphyrin

In dilute aqueous solution the oxidized prosthetic group of hæmoglobin and catalase, ferriprotoporphyrin (the ferric iron derivative of 1,3,5,8-tetramethyl-2,4-divinylporphine-6,7-dipropionic acid) may be affected by ionizing radiation at several places in its complex structure. Dale and Russell[1] and Barron and Johnson[2] observed spectroscopic changes which led them to conclude that the porphyrin ring was broken. In addition, Barron and Johnson found that in the absence of oxygen the spectrum was changed to that of a ferroprotoporphyrin. We have obtained spectroscopic evidence that a new compound is produced before the ring is broken, and that the vinyl side-chains play an important part in its formation. It is also found that hydrogen peroxide will produce this compound.

Irradiation of an aerated 10^{-5} *M* solution of ferriprotoporphyrin in 0·1 *N* sodium hydroxide with 15,000 r. of γ-rays from a cobalt-60 source results in a shift of the visible absorption peak from 612 mμ to 600 mμ and in a small decrease in its intensity. The visible absorption spectra have isosbestic points at about 415, 495, 560, 605 and 640 mμ, which suggests that the reaction is one in which one coloured compound is being changed into another single-coloured compound. Above 15,000 r. a general decrease in intensity of the entire visible absorption spectrum is observed. As the visible spectrum changes during the initial period of radiation, a rapid non-exponential decrease of about 28 per cent in the Soret peak (at 385 mμ) also occurs; this is followed (above 15,000 r.) by a less rapid, exponential decrease. The rate curve based on the decreased absorption of the Soret peak is typical of two consecutive first-order reactions in which compounds *A* and *B* possess the property which is being measured, and *C* does not, and in which the rate of conversion of *A* to *B* is much faster than of *B* to *C*. These observations are in accord with an initial reaction in which a compound, *B*, with an intact porphyrin ring, is produced, followed by reactions resulting in a rupture of the porphyrin ring structure.

Further evidence that compound *B* is an iron porphyrin pigment can be found in its reaction with pyridine. The compound with the absorption band at 600 mμ and the less intense Soret peak at 385 mμ was precipitated by acidifying the alkaline solution, and the precipitate was dissolved in 25 per cent aqueous pyridine. The absorption spectrum of this solution had peaks characteristic of a pyridine ferriprotoporphyrin. When dithionite was added, the spectrum changed to one having visible band maxima at 522 and 554 mμ and a Soret peak at 417 mμ. This spectrum resembles that of pyridine ferroprotoporphyrin, which has visible band maxima at 525 and 556 mμ, and a Soret peak at 420 mμ. It was shown that the new compound was stable to treatment with pyridine by acidifying the pyridine solution, thus precipitating a pigment, the visible absorption spectrum of which in 0·1 *N* sodium hydroxide was identical with that of the 600 mμ compound. Application of this procedure to pyridine ferroprotoporphyrin itself yields ferriprotoporphyrin.

Treatment of alkaline ferriprotoporphyrin with about an equimolar amount of hydrogen peroxide results in changes in the visible and ultra-violet spectra which are difficult to distinguish from those produced by 15,000 r. of γ-radiation. A gradual change in the spectrum could be followed using fractional equivalents of hydrogen peroxide. Isosbestic points were observed at the same positions as in the radiation reaction. Much larger amounts of hydrogen peroxide did not change the position of the bands, but did cause the very slow general decrease in the intensity of the visible and Soret regions of the spectrum reported by Lemberg and Legge[3]. There seems to be little doubt that the reaction of alkaline ferriprotoporphyrin with dilute hydrogen peroxide is closely analogous to that produced by low doses of γ-radiation. Dilute potassium permanganate also reacts with alkaline ferriprotoporphyrin in a similar manner, shifting the 612 mμ peak to 600 mμ.

Evidence of the importance of the vinyl groups of ferriprotoporphyrin on the production of the new compound was obtained by comparative studies with ferrideuteroporphyrin. Irradiation of dilute alkaline solutions of ferrideuteroporphyrin (the ferric iron derivative of 1,3,5,8-tetramethylporphine-6,7-dipropionic acid) prepared by melting ferriprotoporphyrin with resorcinol to remove the side chains in the 2 and 4 positions[4], caused no shifts in the peaks of the visible absorption spectrum, and the decrease in the Soret peak approximates to that of a single first-order reaction. The rate for doses to 10^5 r. is approximately the same as that for a ferriprotoporphyrin solution of the same initial concentration from 15,000–10^5 r. These observations suggest that the initial effect of γ-irradiation on ferrideuteroporphyrin, unlike that on ferriprotoporphyrin, results in a rupture of the porphyrin ring structure. It clearly follows, then, that the vinyl side chains are necessary for the formation of the new compound from ferriprotoporphyrin. Whether they act by activating some other part of the porphyrin molecule, or whether they take part directly in the radiation reaction, or possibly both, however, remains a subject for further research.

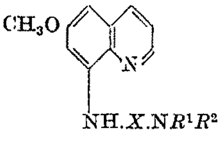
A New Series of Leishmanicides

The first synthetic antimalarial that found a place in medicine was pamaquin (plasmochin), which is an 8-aminoquinoline derivative (I; $X = CHCH_3.[CH_2]_3$; $R^1 = R^2 = C_2H_5$), and since its discovery more than twenty-five years ago[1] many examples of the class have been prepared, of which some exceed pamaquin in antimalarial activity.

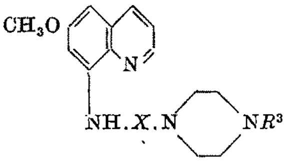
We have now found that a closely defined group of compounds of this class (patent applications pending) possess the rare attribute of chemotherapeutic activity against *Leishmania*, the protozoan parasite which causes kalar-azar and oriental sore.

The substances were tested in hamsters infected with several strains of *Leishmania donovani* by the methods described by Goodwin[2,3]. The active members of the series were more effective than quinquevalent antimonials and aromatic diamidines when given subcutaneously, and unlike the other leishmanicidal drugs, they are also active when given orally.

The essential structural criterion is that piperazino shall be the terminal basic group in place of NR^1R^2, the active class being represented by (II) in which X is a straight or branched alkylene chain.



(I)



(II)

The consequential introduction of a further basic centre is not itself the decisive feature in that compounds such as (I; $X = [CH_2]_2.NH.[CH_2]_2$) are inactive, as indeed are those with other basic terminal rings (for example, morpholino, piperidino, pyrrolidino). Compounds of this class with 5 : 6-dimethoxy and those in which the 6-methoxy- is replaced by a 6-hydroxy- or a 6-ethoxy-group are also active, but 6-chloro- and 6-unsubstituted compounds are without significant activity. A wide variation of the alkylene group X is permitted, and activity is notably high for $X = [CH_2]_3$. Activity is maintained with a variety of N-substituents of the piperazine ring, and is high for $R^3 = H$ or alkyl; compounds with hydroxyalkyl in this position are also very effective. Compounds with substituents in this position, such as CO_2Et, $CO.NEt_2$ or aryl, that suppress or greatly reduce the basic character of the terminal nitrogen atom, are usually inactive.

Some members of the series possess high activity against *Plasmodium gallinaceum* in chicks.

The Morphinized–Eserinized Leech Muscle for the Assay of Acetylcholine

The use of the eserinized dorsal wall of the leech as an assay object for acetylcholine has proved unsatisfactory in the past because of inadequate relaxation and decreasing sensitivity in most preparations.

As Paton *et al.*[1] had shown that morphine decreased the output of acetylcholine in the electrically stimulated ileum of the guinea pig, it was decided to investigate the influence of morphine on the relaxation of the eserinized leech. Morphine was found to facilitate relaxation and in a suitable concentration (4 or 5 × 10^{-5} gm./ml.) did not appreciably decrease the sensitivity to acetylcholine. In a higher concentration (10^{-4} gm./ml. or greater) it depressed the response to acetylcholine as had been previously described by other workers[2].

The dorsal wall was cut longitudinally and horizontally to give four strips. The magnification was 20-fold and the tension equivalent to 2 gm. The composition of the oxygenated Ringer solution was as follows: sodium chloride 9, potassium chloride 0·42, calcium chloride 0·24, sodium bicarbonate 0·15 and dextrose 1 gm. in 1·4 litres of distilled water. The *p*H was 7·3.

Initially the leech strip was immersed in morphine sulphate (4 or 5 × 10^{-5} gm./ml.)–Ringer and left until adequately relaxed, usually 3 hr. or less, the lever being tapped occasionally. The strip was then immersed in morphine (4 or 5 × 10^{-5} gm./ml.)–eserine sulphate (10^{-5} gm./ml.)–Ringer for 30 min. before commencing an assay. The eserine usually caused only a slight contracture. The morphine–eserine–Ringer was used for washing throughout. As the test solutions consisted of mammalian–Ringer perfusates containing 10^{-5} gm./ml. eserine, which were diluted with distilled water (10–14 ml.) before assay, acetylcholine was applied in eserine (7 × 10^{-6} gm./ml.)–Ringer and allowed to act for 1½–3 min. The preparation was washed two or three times and relaxation was facilitated by tapping the lever. Suitable assays were carried out in twenty experiments on eighty strips. On most strips the threshold concentration of acetylcholine was 10^{-9} gm./ml. Occasionally it was 1·5 × 10^{-9} gm./ml. and in two 0·5 × 10^{-9} gm./ml. In no case did the sensitivity fall off during a 3–5 hr. assay. Smoking during an assay did not appear to interfere with relaxation. In one experiment in which the strip was immersed in Ringer containing 7 × 10^{-6} gm./ml. eserine with the morphine proportionally reduced (3 × 10^{-5} gm./ml.), the sensitivity to acetylcholine was decreased. Evidently the concentration of eserine and morphine is critical.

A Reduced Diphosphopyridine Nucleotide Oxidase in Lettuce Seeds

Various enzymes oxidizing reduced diphosphopyridine nucleotide by pathways other than the cytochrome system have been described. Kern and Racker[1] indicated an oxidase dependent on a product of the oxidation of ascorbic acid, and Nason *et al.*[2] have shown the existence of a nucleotide–quinone reductase. Mapson and Moustafa[3] have shown the oxidation of reduced triphosphopyridine nucleotide by an enzyme linked to glutathione, while Kersten *et al.*[4] have demonstrated the existence of an oxidase dependent on ascorbic acid. Hackett[5] has shown that the ascorbic acid oxidase of potato tubers can oxidize reduced diphosphopyridine nucleotide. Dry lettuce seeds seem to contain an enzyme which does not correspond to those previously described.

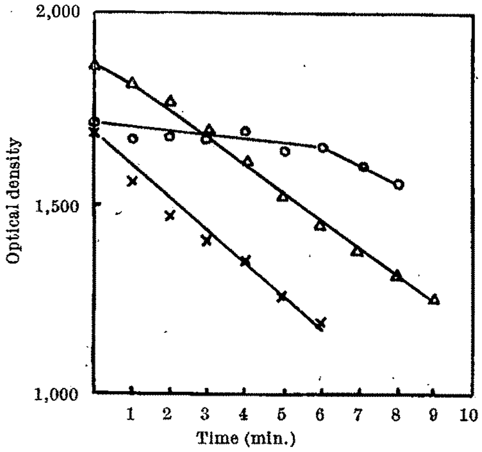

Fig. 1. The oxidation of reduced diphosphopyridine nucleotide in the presence and absence of ascorbic acid. ×, No ascorbic acid added; ○, 0·1 mgm. ascorbic acid/cuvette; △, extract pre-incubated with 0·1 mgm. ascorbic acid for 7 min. before adding reduced diphosphopyridine nucleotide. (Each cuvette contained 1·5 ml. phosphate buffer *p*H 6·3, 0·1 *M*, 0·1 ml. reduced diphosphopyridine nucleotide 0·25 per cent, 0·05 ml. extract and water to 3 ml.)

Extracts of lettuce seeds contain an enzyme which readily oxidizes reduced diphosphopyridine nucleotide without any added hydrogen acceptor. Enzyme activity was followed spectrophotometrically at 340 mμ. The enzyme was not precipitated at 20,000*g* from phosphate–sucrose buffer. The ability of the enzyme to oxidize reduced diphosphopyridine nucleotide was not increased by the addition of cytochrome *c*, reduced or oxidized glutathione, benzoquinone, dihydroxyphenylalanine or dehydrascorbic acid. However, small amounts of ascorbic acid completely inhibited the activity of the enzyme. As the ascorbic acid was destroyed by ascorbic acid oxidase present in the extracts, this inhibition was overcome, but without any increase of activity over corresponding controls (Fig. 1). Thus it appears that no intermediary of the oxidation of ascorbic acid was involved in this reaction. The active extracts also had high dihydroxyphenylalanine oxidase activity. The latter was followed spectrophotometrically at 500 mμ. Both reduced diphosphopyridine nucleotide oxidase and dihydroxyphenylalanine oxidase were inhibited by thiourea and diethyldithiocarbamate. Inhibition of the two systems was similar but not identical. This suggested that the reduced diphosphopyridine nucleotide oxidase is an enzyme containing copper. That it is not ascorbic acid oxidase is shown by its very different sensitivity to thiourea, since this is totally inhibited by $1\cdot 4 \times 10^{-4}$ *M* thiourea, while the reduced diphosphopyridine nucleotide oxidase is totally inhibited only by $1\cdot 3 \times 10^{-3}$ *M* thiourea. Moreover, ascorbic acid oxidase activity rises with increasing time of germination of the lettuce seeds[6], while reduced diphosphopyridine nucleotide oxidase activity falls in the same circumstances. Dihydroxyphenylalanine oxidase activity shows a similar fall in activity. After acetone fractionation, both reduced diphosphopyridine nucleotide oxidase activity and dihydroxyphenylalanine oxidase activity appeared in the same fraction. However, the latter decreased on fractionation, indicating either partial inactivation or some special co-factor requirement. These results suggest that the same enzyme may oxidize both reduced diphosphopyridine nucleotide and dihydroxyphenylalanine. This possibility as well as the co-factor requirement of the enzyme and its physiological importance in lettuce seeds are being investigated. It appears that the enzyme described is not identical with the soluble reduced diphosphopyridine nucleotide oxidases described by other workers[1-4]. Fuller details of this work will be reported elsewhere.

Hypoglycæmic Effect of Monoiodoacetic Acid and Iodoacetamide in Rats

Alloxan lowers the concentration of reduced glutathione in the blood of the rat, but apparently has no effect on reduced glutathione in this animal's pancreatic tissue when the exocrine parenchyma has atrophied as a result of a duct ligation[1]. Nor does it seem to have any effect on the principal islets in certain species of fish[2]. Since alloxan, in both these cases, has a diabetogenic effect the observations seem to suggest that the diabetogenic effect of alloxan is not due to the inhibition of enzymes containing free sulphydryl groups in the β-cells of the islets of Langerhans[3].

Monoiodoacetic acid and iodoacetamide, when administered to rats, lower reduced glutathione in the blood and in pancreatic tissue atrophied as a result of duct ligation[4]. The effect exerted by these substances on blood sugar and the cells of the islets of Langerhans has been studied in rats. First, by the administration of a single dose subcutaneously (monoiodoacetic acid, 0·05 gm./kgm. body-weight, and iodoacetamide, 0·03 gm./kgm. body-weight), and secondly, by giving a daily dose of 0·005–0·01 gm./kgm. body-weight over a period of 15 days. The blood

sugar was determined by Hagedorn and Jensen's method, and the pancreas was stained with chromhæmatoxylin–Ponceau–fuchsin after fixation in Bouin's fluid. The nuclear size of the α- and β-cells was determined with a planimeter after the cells had been sketched at a magnification of approximately 1,700.

After the single dose of monoiodoacetic acid and iodoacetamide (Fig. 1) the blood sugar decreased, reaching its lowest value 3–4 hr. after the injection and returning to its original concentration within 24 hr. of the injection. A certain increase in the values noted a few days after the injection of monoiodoacetic acid could not be statistically demonstrated. After the administration of iodoacetamide the blood sugar values 2–3 days after the injection were lower than those for the control animals, but not lower than the starting value. No permanent increase in blood sugar was observed. When the substances were administered daily, neither hyperglycæmia nor glycosuria developed.

Microscopic examination of the pancreas at varying intervals after the injection did not reveal any necrosis in either of the cell forms in the islets; nor was any pyknosis observed in the nuclei of the islet cells. Great variability in the stainability and granulation, such as is seen in connexion with heightened function, was observed in both α- and β-cells during the 24 hr. immediately following the injection. The result of the karyometric examination can be seen in Table 1. Both forms of islet cells displayed nuclear enlargement, suggesting that increased activity was in progress. This activity persisted, in the β-cells, almost throughout the first 24 hr. after the injection, whereas in the α-cells the disturbance was of short duration. No change in nuclear size could be demonstrated after 24 hr. or after 15 days of continuous administration.

These studies have not revealed anything to indicate that monoiodoacetic acid and iodoacetamide are diabetogenic in the doses used, despite the fact that, in certain respects, they exert a stronger effect on sulphydryl substances than alloxan. The reason for the decrease in blood sugar observed after the injection of monoiodoacetic acid and iodoacetamide seems to lie in the increased β-cell activity which, to judge from the karyometric findings, arises after injection of the single dose. Nothing definite was observed to indicate damage to the α-cells.

Species Difference in regard to the Biosynthesis of Ascorbic Acid

IN previous reports[1] [2] from this laboratory, it has been shown that the liver tissue of mammals such as the cow, goat and rat (but not the guinea pig) could produce strikingly large amounts of ascorbic acid *in vitro* with D-glucuronolactone as substrate in presence of cyanide. This did not occur in the absence of cyanide, and no other substrate except L-gulonolactone was effective. It was, however, found[1,2] that the liver tissue of birds such as the chicken and the pigeon, which are known to synthesize their own requirements of ascorbic acid, failed to synthesize ascorbic acid under these conditions. Grollman and Lehninger[3] have meanwhile shown by their method that, as opposed to mammals, the capacity for synthesizing ascorbic acid in the birds and reptiles they studied, namely, the chicken, pigeon and tortoise, resides in the kidney tissues.

It was of interest to study, by our technique using cyanide, the capacity of different species of animals, including amphibians, reptiles, birds and mammals, to synthesize ascorbic acid. Table 1 shows the results obtained.

Table 1. NET SYNTHESIS OF ASCORBIC ACID (μGM.) BY THE KIDNEY AND LIVER TISSUE HOMOGENATES

The test system contains 0·07 *M* phosphate buffer (*p*H 7·4), 0·025 *M* substrate, tissue homogenate (250 mgm.), 0·05 *M* potassium cyanide in a total volume of 5·0 ml. incubated for 2 hr. at 37·5° C.

Indian fruit bat	*Pteropus medius*	0	0
Rat		0	90

* Passeriformes.

It will be seen from Table 1 that both amphibian and reptile kidney tissues, but not their liver tissues, could synthesize ascorbic acid. The lower value of ascorbic acid obtained with the toad tissue in winter compared with summer is apparently due to its lower metabolism during hibernation in winter. In the cases of the different avian species, in those which are supposed to belong to older natural orders in the evolutionary scale[4,5], namely, the chicken, pigeon, etc., the kidney tissue and not liver could synthesize ascorbic acid. However, in the majority of the species studied belonging to the Passeriformes, a more recent natural order, the liver tissue and not the kidney tissue could synthesize ascorbic acid. In two species belonging to this natural order, namely, the house crow and the common myna, both the liver and kidney tissues could effect this synthesis, the liver being more active than the kidney. But in one species —the red-vented bulbul—belonging to this natural order, neither the liver nor the kidney could bring about the synthesis. It would thus appear that in the natural orders in the earlier stages of evolution, namely, the amphibians and the reptiles, the biosynthetic mechanism for ascorbic acid resides in the kidney tissue. It continues to be so in the different species of birds until in the most recent natural order, the Passeriformes, the liver takes over this function, a few species sharing it with the kidney in a smaller degree and one having both liver and kidney tissues incapable of effecting this synthesis. Thus in the evolutionary ascent this mechanism seems to pass from the kidney to the liver and then to disappear also from the liver.

This is in agreement with the observation that the liver tissues of all lower mammals studied except the guinea pig can synthesize ascorbic acid, but this capacity of the liver is absent in the more evolved primates. Thus in the case of the rat the liver but not the kidney can synthesize ascorbic acid. The case of the flying mammal, the Indian fruit bat, is interesting. We had expected its liver tissue, in common with that of most mammals, to be able to synthesize ascorbic acid, but neither its liver nor its kidney could do so. The bat is supposed to be closely related to the primates, which are known to be unable to synthesize ascorbic acid, and this may be further biochemical evidence for the relationship. These results indicate that although practically all species except the primates and the guinea pig are supposed to be able to synthesize ascorbic acid, it is possible that several of them cannot do so, and the cyanide technique might provide a simple means for determining this capacity.

It may be mentioned that in all these cases, the biosynthesis of ascorbic acid has been found to be inhibited by *p*-chloromercuribenzoate, this effect being reversed by reduced glutathione. This had already been observed with the liver tissue of the rat and goat[2]. It suggests that thiol groups are involved in the enzyme systems concerned, whether they are in the liver or in the kidney tissue. The fact that the enzyme systems of the liver and of the kidney of all species studied operate in the same way with respect to the effect of cyanide, specificity of substrate, effect of *p*-chloromercuribenzoate, etc., indicates that the enzyme systems concerned are identical or closely similar, whatever the species.

We wish to thank Dr. B. Biswas, Zoological Survey of India, and Prof. J. L. Bhaduri, head of the Department of Zoology, University of Calcutta, for their advice and assistance with the identification of the species and the Indian Council of Medical Research for a research grant.

Hæmoglobin and Potassium Blood Types in Some Non-British Breeds of Sheep and in Certain Rare British Breeds

Sheep may be classified into three types, *A*, *B* or *AB*, according to whether they possess one, or another, or a mixture of two distinct hæmoglobins[1-3]. They may also be classified quite independently into two types, *HK* and *LK*, according to whether the concentration of potassium in their whole blood is relatively high or low[4]. Both sets of characters are determined genetically and the genes responsible are at different chromosomal loci[3,5].

In an extensive survey of more than thirty different British breeds of sheep we have been able to show that the majority of these breeds are polymorphic with respect to the genes at both these loci, but that large differences in gene frequency occur from breed to breed[6]. The mountain and hill breeds, particularly those from the northern part of Britain, tend to have rather high frequencies of hæmoglobin *A* and *HK*, while the lowland breeds tend to have high frequencies of hæmoglobin *B* and *LK*. A detailed map of the distribution of these characters in breeds of sheep from other countries would be of obvious help in attempting to assess the biological significance of this kind of polymorphism.

During the past three years we have had the opportunity of examining the hæmoglobin and blood potassium types in a number of breeds of sheep located in widely scattered parts of the world. The data are in many respects incomplete and fragmentary, and the number of animals tested is relatively few. Nevertheless, it seems worth while recording the results at this stage because they do give a rough indication of the frequencies of these characters in sheep from very diverse places, and they may be useful to workers in other countries examining these characters in their local breeds.

Heparinized blood samples were sent by air to England from the various points of collection, and the time taken in transit varied from about three days for the Awasi (Israel) to about twenty-one days for the Merino samples from the Northern Territory of Australia. A proportion of the samples could not be used for hæmoglobin typing because of gross hæmolysis, and occasionally clotting had occurred and this prevented a satisfactory determination of the potassium content of the whole blood. We have, however, no reason to believe that one or another of the blood types were selectively affected in this way.

Table 1. HÆMOGLOBIN AND POTASSIUM BLOOD TYPES IN FOURTEEN NON-BRITISH BREEDS OF SHEEP

Breed	Sample obtained from	Believed place of origin of breed (cf. ref. 11)	Hæmoglobin types					Blood potassium types		
			No. tested	*A*	*AB*	*B*	Estimated frequency of *A* gene	No. tested	*LK*	Frequency of *LK* type
Scandinavian:										
Finnish	Finland	Finland	26	26	0	0	1·0	42	15	0·36
Icelandic	Iceland	Iceland	44	29	14	1	0·82	44	2	0·05
Old Norwegian	Norway	Norway	9	9	0	0	1·0	44	5	0·11
African/Middle East:										
Awasi	Israel	Syria, Israel and Iraq	39	0	0	39	0·0	59	15	0·25
Awasi	Iraq		47	1	3	43	0·05	48	4	0·08
Barki	Egypt	North-West Egypt	37	1	7	29	0·12	42	34	0·81
Blackheaded Persian	Tanganyika	South Africa	21	0	0	21	0·0	46	5	0·11
Fulani	Nigeria	Senegal to Cameroons	60	2	3	55	0·06	69	16	0·23
Masai	Tanganyika	Tanganyika, Kenya, Uganda	30	0	0	30	0·0	42	8	0·19
Rahmani	Egypt	Lower Egypt	43	0	1	42	0·01	43	7	0·16
Merino:										
Northern Territory, Australia	Australia	Spain	37	3	22	12	0·38	39	39	1·00
Rambouillet	France		19	11	8	0	0·79	23	23	1·00
Tasmania	Australia		24	7	14	3	0·58	25	23	0·92
Others:										
Bighorn	Canada (Alberta)	Rocky Mountains (North America)	4	0	0	4	0·0	4	0	0·00

The results are given in Table 1. The distribution of the hæmoglobin types in the Scandinavian breeds contrasts strikingly with that found in the Middle Eastern and African breeds. In the former, hæmoglobin *A* is very common, while in the latter, hæmoglobin *B* preponderates. On the other hand, *LK* is relatively infrequent both in Scandinavia and in the Middle East and Africa (with the single exception of the Barki), and it is clear that the correlation in gene frequencies between *B* and *LK* which occurs in British breeds does not apply here.

The Merinos form a distinctive and peculiar group. The three flocks studied were almost entirely *LK*, a fact which agrees with earlier reports[7,8], but both types of hæmoglobin are fairly common.

The interpretation of the results for *HK* requires special comment. It is thought probable that four types of sheep may occur, with distinctive concentrations of potassium and sodium in the red cells. These have been called[9] $Ke\alpha$, $Ke\beta$, $Ke\gamma$ and $Ke\Delta$. On whole-blood analysis $Ke\beta$, γ and Δ fall into the *HK* group and $Ke\alpha$ into the *LK* group. The distinction between $Ke\beta$, γ and Δ requires determinations of the concentrations of potassium and sodium in the red blood cells using fresh blood. In practice, whole-blood determinations are adequate in most surveys of British breeds of sheep because it has been found that $Ke\beta$ and $Ke\Delta$ are extremely rare in Britain and, therefore, *HK* almost invariably implies $Ke\gamma$. In the Middle East and Africa this is probably not the case, and it is possible that $Ke\beta$ and $Ke\Delta$ may be quite common. In Kerr's data[10] from Lebanese fat-tailed sheep, for example, $Ke\Delta$ was the most common type although all four types were demonstrated. In the present survey the potassium content of the whole blood in the *HK* group was on the average appreciably lower in the Middle Eastern and African breeds than in the Scandinavian breeds and one possible explanation of this is that $Ke\beta$ and Δ types may have been present in the former but not in the latter. Such differences can, however, only be ascertained by detailed studies using fresh blood samples.

Table 2. HÆMOGLOBIN AND POTASSIUM TYPES IN BREEDS OF SHEEP IN THE ZOOLOGICAL GARDENS, LONDON

Breed	Believed place of origin of breed	No. tested	Hæmoglobin types			Potassium types	
			A	*AB*	*B*	*HK*	*LK*
Mouflon	Corsica and Sardinia	4	2	2	0	2	2
Barbary	Libya, Tunisia and E. Algeria	5	0	0	5	2	3
Jacob's (Spanish Piebald)	? Spain ? Hebrides	7	0	6	1	0	7
Manx	Isle of Man	4	0	0	4	4	0
Soay	Hebrides	12	1	0	11	11	1
Old Norfolk Horn	England	7	0	0	7	7	0

It is appropriate also to report here the results we have obtained from testing a small number of sheep at present in the Zoological Gardens, London (Table 2). They include certain rather rare breeds. In fact, the seven examples of the Old Norfolk Horn are probably the only remaining members of this once quite numerous breed. It is notable that in spite of the small numbers involved, four out of the six breeds examined were polymorphic with respect to one or other of the two sets of characters. A further point of interest is that in the Barbary sheep it was possible to carry out determinations of the potassium and sodium in the red blood cells, and the two *HK* animals were found to be $Ke\beta$.

A grant from the Agricultural Research Council to one of us (F. L. W.) has supported this work. We are also indebted to overseas colleagues and the Zoological Society of London for blood samples.

Hæmoglobin *P* (the 'Galveston' Type)

An earlier communication[1] described a new variant of human hæmoglobin tentatively called the 'Galveston type'. This variant appears identical with hæmoglobin L[2] in paper electrophoresis, veronal buffer, *p*H 8·6, 0·05 *M*, but differs from similar types in that it does not separate from hæmoglobin *A* in free electrophoresis, cacodylate buffer, *p*H 6·2–6·9, 0·1 *M*. It is now suggested that this variant (found in a Negro woman, 'MTu', and in one of her two children) be called hæmoglobin *P*. Fig. 1 shows a photograph of the paper electrophoresis pattern of 'MTu's' hæmoglobin sample, compared with those from subjects with sickle cell trait, hæmoglobin *G* trait, and hæmoglobin *Q* trait. (The sample of hæmoglobin *G* trait[3] is from the subject 'AK'; that of hæmoglobin *Q* trait[4] was kindly supplied by Dr. H. Lehmann.) The various types of hæmoglobin in these samples, listed in order of decreasing mobility, are as follows: *A*, *Q*, *G*, *P* and *S*.

In other types of zone electrophoresis (starch block and agar, both in veronal buffer) 'MTu's' hæmoglobin sample is again resolved into two components, similar to those on paper. Quantitative estimation of these was obtained from the starch-block electrophoresis by determining the concentration of the eluted components spectrophotometrically; the proportions were found to be approximately 1 : 1. However, in the recently developed citrate agar method[5], 'MTu's' hæmoglobin sample was again indistinguishable from hæmoglobin *A*.

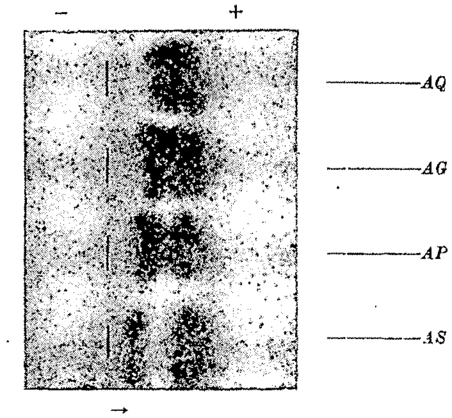

Fig. 1. Paper electrophoresis patterns of hæmoglobin samples *AQ*, *AG*, *AP* and *AS*. Veronal buffer, *p*H 8·6, 0·05 *M*

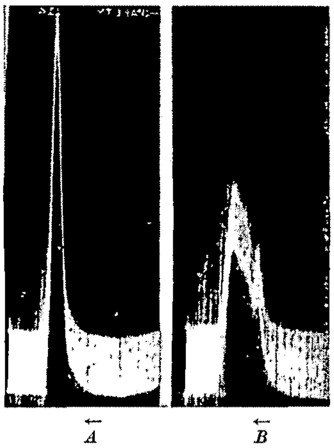

Fig. 2. Scanning diagrams of ascending patterns of 1:1 mixtures of 1 per cent carboxyhæmoglobin samples, cacodylate buffer, *p*H 6·5, 0·1 *M*. *A*, 'MTu's' (*AP*) with hæmoglobin *A*; *B*, 'MTu's' (*AP*) with 'AK's' (*AG*)

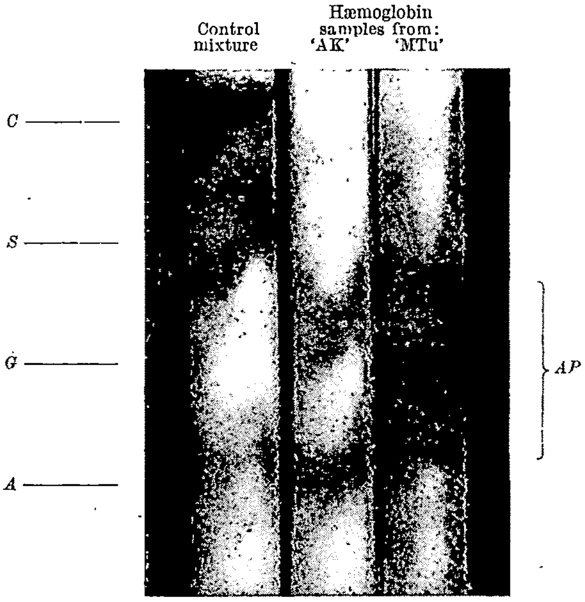

Fig. 3. Chromatography of carboxyhæmoglobin *AP* on columns of 'Amberlite' resin

It has already been noted that in free electrophoresis, cacodylate buffer, *p*H 6·5, μ 0·1, hæmoglobin *AP* migrates as one sharp peak. This was also the case in an analysis with this same buffer of a 1 : 1 mixture of 'MTu's' hæmoglobin sample and hæmoglobin *A* (Fig. 2*A*). Similarly, in free electrophoresis in phosphate buffer, *p*H 6·4, 0·04 *M*[6], the hæmoglobin *AP* of 'MTu's' sample migrates as one sharp peak. The similarity of results with these two different buffers would seem to indicate that in this *p*H range the net charge of hæmoglobin *P* is identical with that of hæmoglobin *A*. However, a lack of true identity is suggested by the fact that in free electrophoresis in cacodylate buffer, mixtures of 'MTu's' hæmoglobin sample with those containing hæmoglobin *S* or *G* develop into two peaks of variable and unpredictable proportions[1], unlike mixtures of *A* and *S* or *G*, which are resolved quantitatively; even more striking is the fact that mixtures of 'MTu's' sample with those containing hæmoglobin *AG* (from patient 'AK') were, on several occasions, resolved into a pattern suggesting the presence of three components (Fig. 2*B*).

Another method of comparing the net charge of various types of hæmoglobin in an acid buffer[7] is that of chromatography on columns of 'Amberlite' resin[8]. In this method hæmoglobin *P* is not sharply differentiated from hæmoglobin *A*, but the diffuse band produced by *AP* in comparison with that produced by *A* suggests again that these two types are not quite identical with respect to net charge in acid buffer (Fig. 3).

In free electrophoresis in an alkaline buffer (veronal, *p*H 8·6, 0·1 *M*), no clear separation was obtained between the *A* and the *P* of 'MTu's' hæmoglobin sample, but the asymmetry of the peak strongly suggested electrophoretic heterogeneity[1]. (In these circumstances the peak produced by *AG* appears relatively symmetrical[9]. This suggests that in free electrophoresis, veronal buffer, as in zone electrophoresis, the mobility of *P* is slightly less than that of *G*.) In an attempt to sharpen this heterogeneity, an aliquot of hæmoglobin *A* was added to an equal amount of 'MTu's' hæmoglobin sample, and the mixture was analysed in free electrophoresis, veronal buffer, *p*H 8·6, 0·1 *M*. It was then resolved into two distinct peaks in both the ascending and descending patterns, and the areas of these peaks were in about the expected proportions (3*A* : 1*P*).

Hæmoglobin *P* may now be characterized as follows: in zone electrophoresis, veronal buffer, *p*H 8·6, the mobility of *P* lies between *G* and *S*, like that of hæmoglobin *L*[2]. In free electrophoresis in acid buffer (cacodylate *p*H 6·2–6·9, 0·1 *M* or phosphate, *p*H 6·4, 0·04 *M*) the mobility of *P* appears identical with that of *A*. However, in analyses of mixtures of *P*, *A* and *G* (cacodylate *p*H 6·5), there is indication that in this *p*H range the net charge of *P* is not precisely the same as that of *A*, but rather that *P* overlaps *A* and *G* in this respect. This is also suggested by the results of column chromatography with 'Amberlite', citrate buffer, *p*H 6·5 (ref. 8). In free electrophoresis in alkaline buffer (veronal, *p*H 8·6, 0·1 *M*) *P* does not separate clearly from *A* in a 1 : 1 mixture of these two types. However, in a mixture containing approximately three parts of *A* and one part of *P*, quantitative separation does occur, and the mobility of *P* (as in zone electrophoresis) is less than that of *A*. Finally, in free electrophoresis at *p*H 6·5 of mixtures of *P* with other types of hæmoglobin, the qualitative and quantitative resolutions of *P* are to a unique extent influenced by the nature of the companion proteins.

Gamma-Amino-*n*-Butyric Acid and Spinal Synaptic Transmission

A MAJOR constituent of factor I isolated from mammalian brain has been shown to be γ-amino-*n*-butyric acid[1]. It has been assumed that this material, an inhibitor of the crayfish stretch receptor, is an inhibitory transmitter substance within the mammalian central nervous system[2]. Recent investigations indeed have shown that γ-amino-*n*-butyric acid reversibly depresses the potentials arising from the synaptic activation of cells within the cerebral cortex[3] but no precise differentiation as to the mode of action of γ-amino-*n*-butyric acid has been attempted.

In the present investigation, γ-amino-*n*-butyric acid has been passed electrophoretically, as a cation, from one barrel of a multi-barrelled electrode. The responses, both of single cells and of groups of cells within the spinal cord of the cat, have been recorded from another barrel of the electrode filled with 4 *M* sodium chloride solution.

In the dorsal horn and intermediate nucleus of the spinal cord, cells caused to discharge by volleys in skin or muscle afferent fibres are prevented from firing by γ-amino-*n*-butyric acid. Similarly in the ventral horn, motoneurones cannot be fired either orthodromically or antidromically under the influence of γ-amino-*n*-butyric acid. In addition, the antidromic responses of small motoneurones, and the responses of Renshaw cells both to synaptic stimulation and activation by ionophoretically applied acetylcholine, are prevented by γ-amino-*n*-butyric acid. All these effects of the acid are evoked by currents of 20–350 × 10^{-9} amp. and are of short latency and rapidly reversible.

In both the dorsal and ventral horns focal synaptic potentials, recorded extracellularly and evoked by simultaneous excitation or inhibition of groups of cells, are diminished or even abolished by γ-amino-*n*-butyric acid. This reduction of excitatory focal synaptic potentials is not altered by strychnine administered intravenously, and is not accompanied by any diminution in the size of potentials recorded simultaneously from the pre-synaptic fibres. Excitatory synaptic potentials, evoked in motoneurones by impulses in group *Ia* afferent fibres, and recorded extracellularly as negative potentials, could be converted into positive potentials, indicating that the membrane behaving as a sink for current had been converted into a source.

These results make it extremely unlikely that γ-amino-*n*-butyric acid is a transmitter substance in the mammalian spinal cord. In particular, the abolition of the excitatory post-synaptic potentials of motoneurones recorded extracellularly excludes the possibility that γ-amino-*n*-butyric acid is the inhibitory transmitter upon these cells. Although it might be expected that excess inhibitory transmitter would lead to hyperpolarization of the cell with abolition of inhibitory post-synaptic potentials, the actual alteration in the membrane conductance would be small[4]. Hence, post-synaptic excitatory potentials would not be abolished and focal synaptic potentials, consisting predominantly of extracellularly recorded excitatory potentials, would still be recorded.

Accordingly, it is probable that γ-amino-*n*-butyric acid has a depressant action on the whole somadendritic membrane of centrally located neurones, both the chemically activated subsynaptic membrane and the remaining electrically activated post-synaptic membrane.

Self-depression of the Subcutaneous Absorption of Drugs due to Release of Histamine

In experiments on the subcutaneous absorption of drugs from injected solutions we have demonstrated a marked self-depression of the subcutaneous absorption, due to histamine released by the injection trauma.

The absorption experiments were carried out by injecting 2 ml./kgm. of an aqueous sulphacetamide sodium solution (50 mgm./ml.) subcutaneously to rabbits and rats, and then determining the concentration of sulphacetamide in the serum at different times after the injection[1,2]. Both in rabbits (Fig. 1) and in rats (Table 1) the concentrations in serum, compared with control experiments, were markedly lowered for the first 20 min. after the injection, when histamine hydrochloride (90 μgm./ml.) was added to the injection fluid. Histamine dilates capillaries and enhances their permeability. Therefore, delayed absorption is possibly due to the preponderance of the transcapillary filtration during the formation of the œdema provoked by histamine.

Table 1. CONCENTRATION OF SULPHACETAMIDE IN SERUM (μGM./ML.) FROM RATS, 5 MIN. AFTER SUBCUTANEOUS INJECTION OF 2 ML./KGM. OF A SULPHACETAMIDE SODIUM SOLUTION (50 MGM./ML.)

Pre-treatment	No. of experiments	Mean	Standard error of mean	*P*
Controls	16	53·6	± 2·5	
Histamine locally	9	38·3	± 4·5	< 0·001
Histamine depleted	10	71·4	± 3·1	< 0·001
Mepyramine	8	77·7	± 2·5	< 0·001

In experiments on rats, where the concentration of sulphacetamide was determined in serum 5 min. after the subcutaneous injections, depletion of the tissue histamine content and blocking the sensitivity to histamine by mepyramine maleate gave a pronounced and statistically significant rise in the concentrations measured, when compared with the results from experiments on untreated animals (Table 1). The difference amounted to about 30 per cent. The histamine depletion was brought about with compound 48/80, giving 0·25, 0·50, 0, 1·0, 1·0, 0, 1·5, 2·0 and 2·5 mgm./kgm. intraperitoneally in a 1/2,000 solution in saline (8·5 mgm./ml.) on the first to the tenth day. Absorption experiments were performed on the eleventh day. 50 mgm./kgm. mepyramine maleate (25 mgm./ml. in saline, 8·5 mgm./ml.) was given in a single dose intraperitoneally 45 min. before the absorption experiments.

The results mentioned above have been confirmed in absorption experiments on rats with subcutaneous injection of 5 ml./kgm. morphine hydrochloride (20 mgm./ml.) solution, in collaboration with Kirsten Milthers, using a method for the determination of small quantities of morphine in blood, developed by Milthers[3]. Morphine is known to be a chemical histamine liberator. Therefore a marked self-depression of the subcutaneous absorption of morphine was expected. This view was confirmed by the experimental results. The concentration of morphine in the blood 10 min. after a subcutaneous injection is 100 per cent higher in rats depleted of histamine or treated with mepyramine (7·5–10 μgm./ml.) than in untreated control animals (about 4 μgm./ml.).

From the experimental results, I suggest that the subcutaneous absorption of drugs is normally reduced for the first 20 min. after the subcutaneous injection due to a self-depression caused by release of tissue (mast-cell) histamine. When the injected drug is a chemical histamine liberator, such as morphine, the self-depression is very pronounced. When the injected drug is without chemical histamine-releasing activity, only the injection trauma and the injection of a non-physiological fluid (which a drug solution is) provoke a lesser liberation of histamine, giving a smaller, but qualitatively similar, self-depression of the absorption-rate.

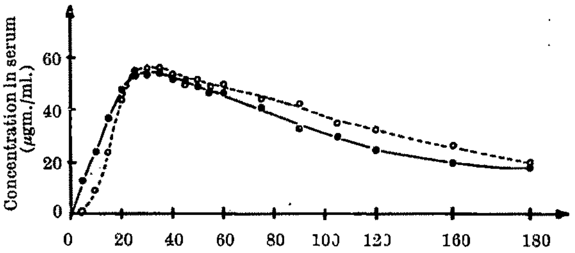

Fig. 1. Mean curves showing the concentration in serum (μgm./ml.) from three cross-over absorption experiments on rabbits given 2 ml./kgm. sulphacetamide sodium (50 mgm./ml.) subcutaneously on the abdomen. ●——●, Controls; ○– – –○, experiments with histamine hydrochloride (90 μgm./ml.) added to the injection solution

I am grateful to Prof. Knud O. Møller, for his interest in this work, and to Dr. A. C. Withe, of the Wellcome Research Laboratories, for a sample of compound 48/80.

Level of Liver Glycogen in Ketosis

SINCE von Mering and Minkowski[1] showed that the liver of the depancreatized dog contains little glycogen, it has been widely held that the degree of ketosis is inversely proportional to the level of liver glycogen. Thus Mirsky[2] believes that ketogenesis in diabetes mellitus arises either as a result of glycogenolysis or when the liver glycogen has fallen to a critical level. Burn and Ling[3] have shown that the same relationship holds for the normal rat on a high fat diet. However, evidence is accumulating which shows that this inverse relation is by no means invariable. Appreciable quantities of hepatic glycogen have been found in severely diabetic subjects[4], and in ketotic rats after alloxan administration[5]. It has been shown in this laboratory that in the intact normal rat it is possible to obtain a very high ketonæmia concomitant with high levels of liver glycogen.

Female rats were fasted for 24 hr. to reduce the liver glycogen to minimal levels and then placed on a diet of filtered butter fat (plus 3 per cent salts). 7 gm. of the diet were fed to each rat daily, the portion not consumed voluntarily being administered by stomach tube. The course of the ensuing ketonæmia and ketonuria (Fig. 1) was followed by the method of Mayes and Robson[6]. After 7 days the rats were killed by cervical fracture and the left lateral lobe of the liver assayed for glycogen. Fat was estimated in the remainder of the liver by extraction with ether. Since the glycogen- and fat-levels of the

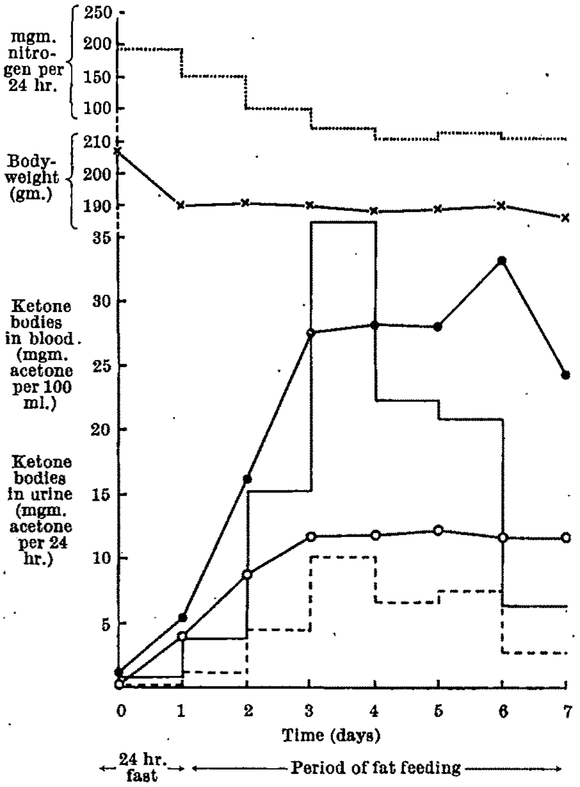

Fig. 1. The course of ketosis in rats (mean of three) starved for 24 hr., then fed 7 gm. per day of butter fat. ●, β-Hydroxybutyric acid in blood; ○, acetone plus acetoacetic acid in blood; ——, β-hydroxybutyric acid in urine; — — —, acetone plus acetoacetic acid in urine; ×, body-weight; ····, total nitrogen in urine

liver fluctuate widely under varying conditions, they are expressed in terms of the glycogen-free, fat-free dry liver weight. The experiments were carried out during the month of May.

Fig. 1 shows that the ketonæmia rose rapidly and after the third day remained at a high level. The ketonuria reached a maximum and thereafter subsided considerably. Seemingly, the apparent renal threshold for ketone bodies changed during the course of the experiment. The individual values at death for liver glycogen and fat are shown in comparison, with the corresponding ketonæmic levels (Table 1). Normal or appreciable quantities of liver glycogen were found to co-exist with a high ketonæmia. Moreover, the liver fat was substantially elevated, thereby demonstrating the lack of any mutual exclusion effect with glycogen. Increased gluconeogenesis from protein was not responsible for the accumulation of glycogen in the liver, as the levels of total urinary nitrogen remained depressed.

Table 1. LEVELS OF KETONÆMIA, LIVER GLYCOGEN AND LIVER FAT IN RATS STARVED FOR 24 HR. THEN FED 7 GM. PER DAY OF BUTTER FAT FOR SIX DAYS

	Total ketone bodies in blood (mgm. acetone/100 ml.)	Liver glycogen		Liver fat	
		Total (mgm.)	gm./100 gm. of glycogen and fat-free dry weight	Total (mgm.)	gm./100 gm. of glycogen and fat-free dry weight
Rat 1	16·44	279	23·1	1,200	99·2
Rat 2	40·82	139	10·8	885	68·6
Rat 3	50·00	190	14·7	1,023	79·0
Normal fed controls (3)	1·63*	335	21·4	146	9·42

* Mean initial level of experimental rats fed butter fat.

The general and undisputed occurrence of ketosis when the liver glycogen-level is low provides the best evidence for an inverse relation. The finding of ketosis in the presence of high concentrations of liver glycogen need not necessarily invalidate this concept. The present results may be interpreted as indicating that in the normal animal a non-glycogenolytic ketogenic factor (or factors) is able to operate, the effect of which is superimposed on the inverse relation between the level of liver glycogen and the degree of ketosis. It is noteworthy that Houssay[7], and others, have described hormonal preparations of the anterior pituitary gland which possess these properties. Such a mechanism could account adequately for the variations in severity of ketosis in diabetic and non-diabetic animals which cannot be explained by the level of liver glycogen alone.

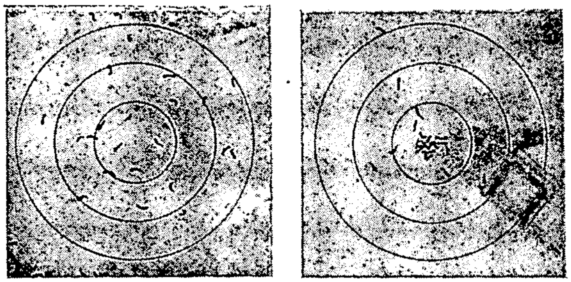
Substances in Mulberry Leaves which attract Silkworm Larvæ (*Bombyx mori*)

ALTHOUGH the larvæ of silkworms eat a few kinds of leaves other than mulberry leaves, for example, fig and lettuce, these do not support normal growth. Proteins and carbohydrates are necessary food substances, but are incapable of acting as attractants, since they are odourless. Experiments showed that mulberry leaves placed within 3–4 cm. of silkworm larvæ did attract them. An investigation was carried out on thirty-eight species of leaves as to the chemotaxis of silkworm larvæ[1]. It was found that substances which attract silkworm larvæ exist widely in green plants, but that the degree of attractivity differs. The leaves of soya bean, mulberry and tea had the strongest attractivity, but the silkworm larvæ gathered around them without eating them. On the other hand, silkworms exhibited a weak chemotaxis to the leaves of fig and lettuce, but ate them when hungry.

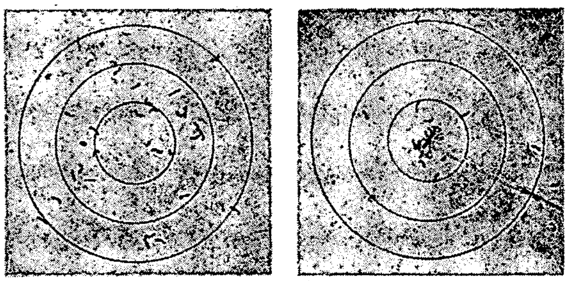
Commercially available organic acids, aldehydes, alcohols and ketones, which are present in green plants, were investigated as to the chemotaxis of silkworm larvæ, but had little effect[1]. *iso*Valeraldehyde, which is known to attract flies[2], hexyl alcohol and *iso*amyl alcohol were slightly positive.

Volatile substances were separated from mulberry leaves by steam distillation. Approximately twenty types of compound were identified as derivatives: alcohols as 3,5-dinitrobenzoates; aldehydes and ketones as 2,4-dinitrophenylhydrazones; and acids as p-phenyl phenacyl esters[3–6].



No attractant Attractant—neutral fraction (b.p. 120–170° C.)

Fig. 1. Attractivity of the essential oil from mulberry leaves for the silkworm larvæ



No attractant Attractant—β-γ-hexenol

Fig. 2. Attractivity of β-γ-hexenol

The neutral fraction from the essential oil of mulberry leaves, especially that with b.p. 120–170° C., attracted silkworms[1]. *n*-Butanol and β-γ-hexenol were detected as alcohols[5], and *n*-butyraldehyde, *iso*butylaldehyde, *n*-valeraldehyde, α-β-hexenal and methyl-ethyl ketone as aldehydes and ketones in this fraction[3,4]. All the compounds other than β-γ-hexenol and α-β-hexenal had already been tested as to their effects on the chemotaxis of silkworm larvæ.

β-γ-Hexenol and α-β-hexenal could not be obtained in the free state from mulberry leaves. These compounds were obtained from the essential oil of *Mentha rotundifolia* L. according to the method of Takei[7]. β-γ-Hexenol attracted the silkworm larvæ strongly. α-β-Hexenal, made by oxidation of β-γ-hexenol, also showed attractivity.

From these experiments it was concluded that the compounds in mulberry leaves which attracted the silkworm were β-γ-hexenol and α-β-hexenal. The larvæ when young tend to be attracted to β-γ-hexenol, and to α-β-hexenal when older.

I am much indebted to Prof. G. S. Fraenkel for helpful discussion.

Reversal by Magnesium Ions of the Inhibition of Yeast Metabolism by a Cationic Detergent

It has been shown[1,2] that cationic detergents strongly inhibit the production of acid and of carbon dioxide by unbuffered suspensions of baker's yeast. It has also been found[2] that the addition to such suspensions of inhibitory concentrations of cationic detergents is followed by extensive lysis of the cells. The suggestion has been made[2] that interaction between detergent cations and anionic groups in the cell surface is an essential factor in the lytic and inhibitory action of cationic detergents on yeast. It seemed possible, therefore, that the inhibition of yeast metabolism by these compounds might be considerably modified in the presence of appropriate concentrations of univalent and bivalent metallic cations which have been shown[3] to combine with at least two types of fixed anion in the yeast cell surface.

The effect of magnesium ions (added to the system as magnesium sulphate) on the inhibition of the aerobic carbon dioxide output of a 1 : 20 suspension (in 5 per cent glucose) of baker's yeast by the cationic detergent dodecyl trimethyl ammonium bromide is shown in Fig. 1. Curve 1 of this figure shows the effect of increasing concentrations of magnesium sulphate in the presence of 0·0025 *M* detergent. It is seen that the degree of inhibition decreases from about 93 per cent in the absence of salt to less than 40 per cent in the presence of 0·004 *M* magnesium sulphate. Curve 2 shows the effect of magnesium sulphate, over the same concentration range, on the inhibitory action of a slightly smaller concentration of detergent (0·002 *M*). In this case the degree of inhibition was reduced from some 85 per cent in the absence of salt to about 10 per cent in the presence of 0·004 *M* magnesium sulphate.

It appears that this effect is observed only when the salt is added to the suspension before or at the same time as the detergent. It is seen from Fig. 1 (curve 4) that the addition of magnesium sulphate (up to 0·003 *M*) to yeast suspensions which had been exposed, for 30 min., to 0·0025 *M* dodecyl trimethyl ammonium bromide did not result in any observable increase in fermentative activity.

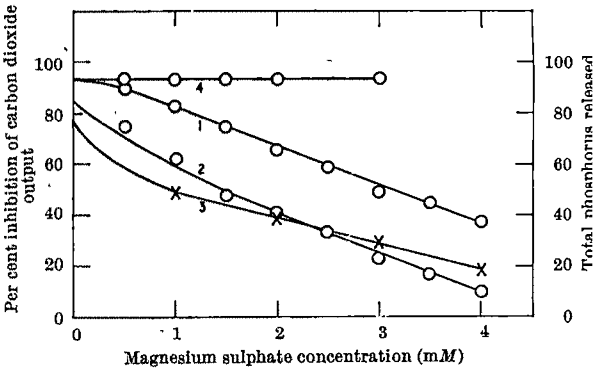

Fig. 1. Effect of magnesium sulphate on the inhibition by dodecyl trimethyl ammonium bromide of the aerobic production of carbon dioxide by baker's yeast (curves 1, 2 and 4). Yeast suspension; 1 part by weight in 20 vol. suspension fluid containing 5 per cent glucose. Detergent concentrations; 0·0025 *M* (curves 1 and 4) and 0·002 *M* (curve 2). Curves 1 and 2, detergent and salt added simultaneously to suspension. Curve 4, detergent added 30 min. before salt. Curve 3, effect of magnesium sulphate on the release of total phosphorus (expressed as a percentage of the amount extracted from the cells by 10 per cent trichloracetic acid) from yeast cells by dodecyl trimethyl ammonium bromide. Yeast suspension, 1 : 20 without glucose

The effect of magnesium sulphate on the lysis of yeast cells by 0·002 *M* dodecyl trimethyl ammonium bromide is shown in curve 3 of Fig. 1. In these experiments lysis was measured in terms of the total amount of the phosphorus released from the cells, this being expressed as a percentage of the total phosphorus extracted from them by 10 per cent trichloracetic acid[2,4,5]. It is seen that there is a progressive decrease in the degree of lysis with increasing magnesium sulphate concentration and that there is a fairly close correlation between the effect of magnesium sulphate on the lytic activity of the detergent and on its inhibitory action on yeast metabolism.

That the reversal, by magnesium sulphate, of the inhibitory action of dodecyl trimethyl ammonium bromide on the aerobic carbon dioxide output of yeast described above may be ascribed to an effect, on the cells, of the magnesium ion is indicated by the fact that similar results are obtained in the presence of other metallic cations which do not themselves inhibit yeast metabolism, and that these results do not appear to depend, to any marked extent, on the nature of the added anion. In the case of salts of bivalent metals (for example, calcium chloride, strontium nitrate, barium chloride, ferrous sulphate, cobalt chloride) the results obtained indicate that the ability of bivalent cations to reverse the inhibitory action of dodecyl trimethyl ammonium bromide on yeast metabolism is, in general, of the same order as that of magnesium ions. The univalent ions tested (lithium, sodium, potassium and ammonium) appeared to be considerably less effective than magnesium ions while the trivalent lanthanum ion showed markedly greater activity than magnesium.

I consider that these results may be interpreted as indicating that magnesium and other metallic cations can, under appropriate conditions, compete with dodecyl trimethyl ammonium bromide for fixed anionic sites on the yeast cell surface.

These experiments were carried out during the tenure of a fellowship of the Medical Research Council of Ireland at the Department of Physiology, University College, Dublin. They will be published in detail elsewhere.

Survival of Intact Insects immersed in Liquid Oxygen without any Antifreeze Agent

It is well known that various organisms can be cooled to very low temperatures in liquid gases without injury, provided that they have previously been desiccated to some extent. Extracellular freezing is considered to be a mode of dehydrating living cells; and some organisms, at least frost-resistant ones, may withstand freezing of this type even at very low temper[illegible]s. On the other hand, many living organisms [illegible]e slow cooling to extremely low temperatures[1]. This might also be explained by dehydration due to extracellular freezing. In these cases, however, the materials used were usually isolated cells or very small pieces of tissue. The largest entire animal hitherto found to survive freezing at a very low temperature is the tiny vinegar eel[2]. Our experiments show that, after sufficient extracellular freezing, an intact insect can be kept alive at an extremely low temperature without any antifreeze agent.

We used a 'slug caterpillar', *Cnidocampa flavescens* (Walk.) in the overwintering prepupal stage, when these insects form hard cocoons in which they complete their metamorphosis in the succeeding summer. The naked prepupal larvæ from the cocoons usually range from 250 to 450 mgm. in weight; they are very resistant to intense cold as well as to prolonged body freezing[3]. The freezing process of the larva is probably as follows[4]. At first, when cooled below about – 20° C., the blood freezes rapidly and then extracellular freezing of the tissue cells occurs. The tissue cells undergo dehydration and contraction; nevertheless they usually withstand such severe conditions for a long period, provided the rate of cooling is not too great.

In our experiments the larvæ in their cocoons were first frozen in a special refrigerator, in which the air temperature was lowered from – 5° to – 90° C. in 1½ hr. and maintained at that temperature for 45 min. The insects were then rewarmed in air at room temperature. After thawing, about one-third of the sixty larvæ revived.

This result suggested that, after partial dehydration due to extracellular freezing, the insect might survive even rapid cooling to a very low temperature, and encouraged us to try freezing the same animal in liquid oxygen after preliminary freezing at graded temperatures.

100 insects were divided into five groups, each of ten larvæ in intact cocoons and an equal number from which the cocoons had been removed. The first group was stored at 0° C. The second was kept for one day at – 10° C., at which temperature the insect never freezes spontaneously[3]. The third was also kept at – 10° C. for one day after the larvæ had been subjected to freezing at – 20° C. The fourth and the fifth groups were held for one day at – 20° C. and – 30° C. respectively, at which temperatures the larva usually freezes within 40 min. All five groups of insects were then immersed directly in liquid oxygen. After being kept there for a full day, they were held in air at – 30° C. for 4 hr. and then transferred into air at room temperature. Among the five groups, revival of the insects after thawing occurred only in the last. Of ten naked larvæ, nine recovered the active movement of the heart which was easily visible through the dorsum. None of them, however, pupated even after incubation at 20° C. for fifty days, nor did the larvæ in intact cocoons, at least within fifty days of incubation. Control insects, stored at 0° C. and then incubated at 20° C., usually completed metamorphosis within fifty days.

A preliminary experiment showed that the tissue cells of this larva are not affected by freezing for several days at – 40° C., provided that the ice formed is extracellular. In the larvæ of the fifth group, most of the tissue cells appeared to be quite normal immediately after thawing except for the fat cells, in which the small fat granules of uniform size sometimes fused into larger homogeneous masses. In the larvæ of all the other groups a remarkable destruction of the fat body usually took place, and when the insect body was dissected numerous small oil droplets, which had flowed out from the fat cells, were observed on the blood surface. In this case some of the tissue cells probably froze intracellularly, whereas in the fifth group most of the cells must have frozen extracellularly. It is therefore reasonable to suppose that if the insects are previously frozen extracellularly at – 30° C., scarcely any water crystallizes in the tissue cells even at an extremely low temperature.

Similar results were obtained from experiments on the overwintering larva of a butterfly, *Aporia crataegi adherbal* Fruhstorfer. The body-weight of this larva was about 1·7 mgm. Two groups of about fifty larvæ in the hibernacula were frozen at – 20° C. and – 30° C. respectively for one day and then immersed directly in liquid oxygen for a full day. After thawing in air at room temperature, all the larvæ prefrozen at –20° C. were found to have been killed, whereas most of the larvæ prefrozen at – 30° C. recovered their motility and have been growing normally on the leaf of apple, the food plant.

Further details of this work will be published elsewhere.

Ultra-structure of the Coxal Glands of the Scorpion

ALTHOUGH much is known, nowadays, about submicroscopic structures of the vertebrate kidney, we still have very poor information on the ultra-structure of invertebrate excretory organs.

Beams *et al.*[1] have studied the cells of grasshopper Malpighian tubules with the electron microscope. They also referred to unpublished evidence concerning the 'nephron' tubule cells of the crayfish. In both cases it appears that some particular features are common to these excretory cells and to vertebrate nephron cells. The most characteristic of these features is the great amount of mitochondria between double membranes which are infoldings of the basal cell membrane.

Coxal glands of the scorpion are embryologically homologous to the kidneys of the crayfish. As a part of a more comprehensive study of their anatomy, cytology and physiology, we investigated the ultra-structure of these organs.

The gland, which is more or less spherical, consists of two parts : (1) a medulla, which has much the same structure as the glomus of a vertebrate nephron but is, of course, devoid of any capillary endothelium, and (2) a cortex, consisting of one single convoluted tubule, arising from the central glomus, and twisted and coiled around it so as to give the whole gland a brain-like appearance. The wall of the tubule is a one-layer epithelium of flat prismatic cells. Even at optical magnifications, these cells have much the same appearance as those of the proximal convoluted tubule of the vertebrate nephron.

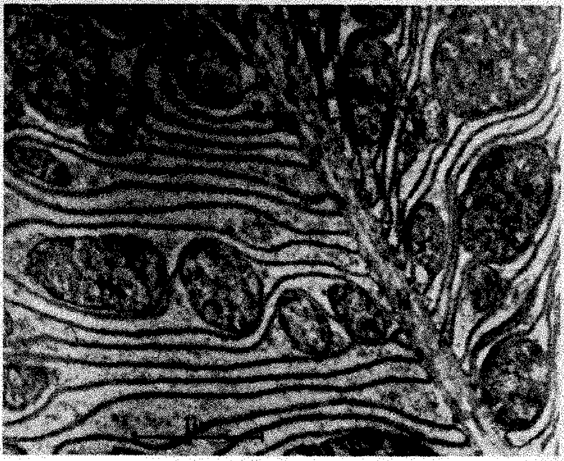

Fig. 1. Basal β-cytomembranes in two coxal gland cells of *Euscorpius carpathicus*. *H*, Hæmolymphatic space between the cells of two adjacent tubules ; *M*, mitochondria (in a fed animal)

On electron micrographs the similarity is striking. (1) In the basal half of the cells a crowd of mitochondria is intricately aligned in narrow compartments and separated by double membranes. (2) These membranes appear to be in every respect similar to those described by Sjöstrand and Rhodin[2] and later called 'β-cytomembranes' by Sjöstrand[3]. They are very narrow infoldings of the thin osmiophilic cell-membrane, running deep into the cell from its base. (3) At the very base of the cell, just outside this folded membrane, there is another membrane. This poorly defined, less osmiophilic layer, is probably the basement membrane of the epithelium. From optical sections, it appears to be continuous with the membrane of the glomerular wall. (4) The mitochondria are disposed in the same way as in vertebrate nephron cells. Nevertheless, their shape is quite different. Instead of being long and cylindrical, with more or less regularly spaced parallel cristæ[4], they are ovoid, with diameters of about 0·5 and 1·5μ. Their inside is a confused mass of twisted irregular cristæ, giving the whole mitochondrion a dense appearance. (5) The upper half of the cell contains a giant nucleus and a few mitochondria. They are scattered throughout the cytoplasm, particularly right under the free limit of the cell. (6) This apical limit is differentiated into a typical brush border. On electron micrographs this border clearly consists of a covering of very long microvilli, densely packed together over the whole surface. The optical microscope shows that the brush-border only extends over the proximal part of the convoluted tubule, that is, on the segment nearest the central glomus. (7) A comparison between coxal glands of starving and well-fed scorpions has shown a great difference between their respective mitochondria. In unfed animals, only a few, well-defined cristæ project into the mitochondrion, in a matrix that appears quite transparent to electrons. Rouiller and Gansler[5] showed the same kind of difference between the mitochondria of the proximal convoluted tubule in normal and starved rats.

The close similarity existing between the ultra-structure of the coxal glands and that of other organs which are known to be excretory suggests that the coxal glands should also be regarded as excretory organs. Although this has been assumed hitherto, it was never demonstrated convincingly. In further work one of us will collect more evidence about the exact function of the gland.

Immuno-chemical Observations on the Intimate Structure of Human Albumin

Marrack and Orlans[1], in a careful study of the behaviour of bovine albumin before and after acetylation, demonstrated that the acetylated product interacted with an antibody globulin prepared against the unmodified bovine albumin.

In a detailed study of globulins isolated from patients suffering from myelomatosis it was noted that individual globulins, homogeneous by electrophoretic and ultracentrifugal analysis, and demonstrably different from one another by these criteria, showed a common behaviour to specific antibodies to the γ_2-globulins using the technique of Ouchterlony or Oudin[2].

These observations prompted us to examine to what extent and in what way a well-characterized human albumin might be modified without materially altering its behaviour to an antibody specific to it in its natural unaltered state.

In a detailed study of the interaction of native and specifically modified albumin with metals in this laboratory, Perkins[3] had prepared a number of modifications of human albumin. Of these we examined three, choosing them because of their satisfactory analysis in the ultracentrifuge and by electrophoresis. The first modification was an acetylated albumin in which analysis indicated that about sixty amino-groups had been replaced by —NHCOCH$_3$. The second and third modifications were the products of interaction of human albumin with bromacetic acid and β-bromopropionic acid respectively. Analysis of the bromacetylated derivative indicated that thirty-six amino-groups had been substituted. The evidence from the behaviour of the protein with various metals suggested that the substitution involved the replacement of both hydrogens in the amino-groups to give —N(CH$_2$COOH)$_2$.

The bromopropionic derivative involved sixty-three amino-groups, the substitution most probably being that the free —NH$_2$ had been converted to —NH(CH$_2$)$_2$COOH.

The original batch of human albumin used in this work gave a value of eighty-seven free amino-groups in 10^5 gm. of protein.

The original albumin and the three modifications were examined by the micro-immunochemical technique of Cleve and Schwick[4] based on the method of Grabar and Williams[5].

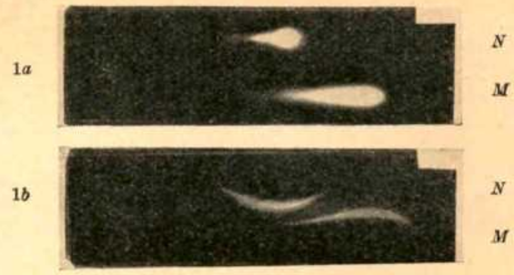

Fig. 1. Acetylated albumin. *a*, Electrophoretic analysis in agar. Analysis carried out at 20°, 2 V./cm. for 2 hr., in glycine buffer *p*H 8·4, ionic strength 0·05. *b*, Immuno-electrophoretic analysis in agar. Analysis carried out as above, followed by development with specific antisera for 18 hr. at 25°

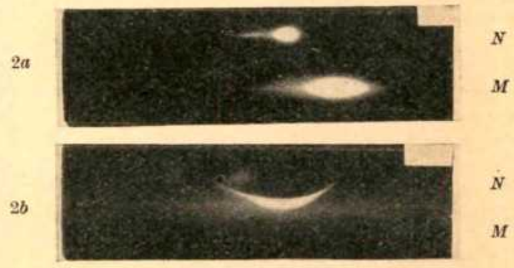

Fig. 2. Albumin modified with bromacetic acid. *a*, Electrophoretic analysis in agar, as in 1*a*. *b*, Immuno-electrophoretic analysis in agar, as in 1*b*

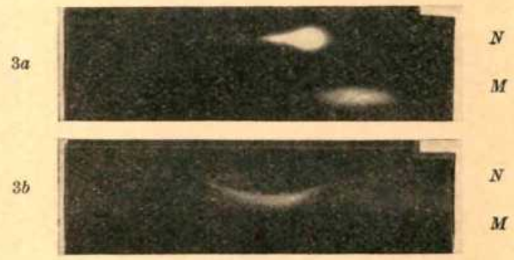

Fig. 3. Albumin modified with bromopropionic acid. *a*, Electrophoretic analysis in agar, as in 1*a*. *b*, Immuno-electrophoretic analysis in agar, as in 1*b*

N, Native albumin; *M*, modified albumin

The replacement of 69 per cent of the free amino-groups with acetylated amino-groups in the first modification materially alters the net charge of the albumin and as a consequence its mobility. This is clearly indicated in Fig. 1*a*. The interaction with antiserum specific for unmodified human albumin is shown in Fig. 1*b*.

From these figures it is clear that proteins may differ markedly in their net surface and in their electrophoretic mobility, and yet retain their capacity to react with specific antisera.

The great proportion of the free amino-groups in albumin are the epsilon amino-groups of lysine. There is no reason to suppose that the majority of the lysine residues are concentrated in one area of the chain; therefore, to have acetylated 69 per cent of the available free amino-groups seems to imply a modification over a considerable surface area of the molecule without altering its capacity to interact with the specific antibody.

Fig. 2*a* shows the relative migration of the unmodified albumin and of the albumin after modification with bromacetic acid (lower spot). Fig. 2*b* shows the well-defined crescent of interactions between the unmodified albumin and antisera specific for unmodified albumin using the immunochemical technique and on the same plate a parallel analysis of albumin modified by bromacetic acid, which fails to react with the specific antisera to produce a precipitate. Albumin modified by bromopropionic acid (Figs. 3*a* and *b*) behaved in the same way as albumin modified by bromacetic acid.

In the second and third modifications the free amino is replaced not by a non-polar group but by a carboxyl carrying a negative charge. There is, therefore, an alteration in net charge not from the reduction in the total of existing positively charged groups but by the replacement of certain of the positively charged with negatively charged groups. This may have a much greater effect on the secondary structure of the protein by redistributing the pattern of surface charge and may actively interfere with the normal hydrogen bonding within the chain. The resulting re-orientation would explain the failure of the modified protein to react with the antisera.

Lunar Periodicity of Aquatic Insects in Lake Victoria

DESPITE the constancy of their environment, certain aquatic insects in Lake Victoria exhibit periodic emergence. In the mayfly, *Povilla adusta*, emergence is closely synchronized and occurs shortly after full moon[1]. On the other hand, most swarms of 'lake-flies' (unidentified Chironomidae and *Chaoborus*) have been reported to occur shortly after new moon[2].

To investigate this matter further, a Robinson-type insect trap[3], fitted with a 125-W. mercury vapour bulb, was run near the lake-shore at Jinja (lat. 0° 25·5′ N.) for a hundred consecutive nights. The numbers caught each night of certain species of Plecoptera, Ephemeroptera, Trichoptera, Chironomidae and *Chaoborus* were counted or estimated, a procedure made feasible by modifying the trap so as to admit only about a quarter of its normal catch.

Of the thirty-seven species studied, four (apart from *P. adusta*) showed a periodic fluctuation in numbers correlated closely with the age of the moon. These species differed, however, as to the position of the peak of abundance in the lunar cycle and as to the amplitude of the fluctuation. Results for these species and for *P. adusta* are given in Table 1.

Table 1. LUNAR PERIODICITY OF FIVE AQUATIC INSECTS IN LAKE VICTORIA

Group	Species	Age of moon to nearest day	
		Abundance peak	Range of captures
Ephemeroptera : Polymitarcidae	*Povilla adusta* Navas	17–18	15–4
Trichoptera : Leptoceridae	*Athripsodes stigma* Kimmins	23–29	Every day
	Athripsodes ugandanus Kimmins	8–9	Every day
Diptera : Chironomidae	*Clinotanypus claripennis* Kieffer	7–8	28–11
	Tanytarsus balteatus Freeman	2–5	Every day

In addition, the estimated abundance of *Chaoborus edulis* Edwards (probably including a few *C. pallidipes* Theo.) also fluctuated in phase with the moon. Numbers rose abruptly to a peak five to two days before new moon (that is, at a moon age of 24–27 days), and thereafter fell gradually, so that there were several nights during the fortnight preceding a peak on which no specimens were found.

That catches in a light-trap may reflect activity as well as emergence or abundance of insects has frequently been emphasized, and it is important where possible to assess the relative effects of these factors. The asymmetrical pattern of abundance of *C. edulis* gives a firm indication that here it is caused primarily by a corresponding rhythm of emergence rather than activity. Observations of five day-time swarms of *Chaoborus* at Jinja, all of which have been 4–2 days before new moon, support this.

The more symmetrical pattern of abundance of *Tanytarsus balteatus* (Fig. 1) might appear at first to support the idea, recently discussed[4], that catches in a light-trap are greatest near new moon and least near full moon owing to an artefact effect resulting from changes in the relative brightness of the trap at different phases of the moon. However, positions of the peaks and troughs relative to new and full moon do not confirm this interpretation, and it appears more likely that the pattern is caused by a lunar rhythm of emergence in which the population is poorly synchronized. The same is possibly true of *Athripsodes stigma* and *A. ugandanus*.

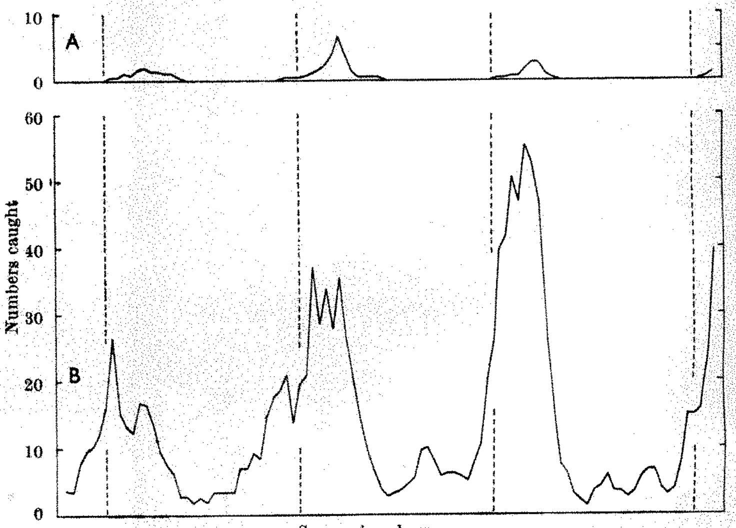

Fig. 1. Numbers caught nightly of (*A*) *Clinotanypus claripennis* and (*B*) *Tanytarsus balteatus* in relation to new moon (shown by vertical dotted lines). Results smoothed by a sliding geometric mean of 3

In the remaining species studied, no cyclical fluctuation in numbers could be discerned. This has two implications of interest: first, it demonstrates that emergence and reproduction of many aquatic insects in equatorial lakes need not be cyclical; and second, it shows that, in the groups studied, the hypothetical artefact effect mentioned above does not influence catches in a light-trap to a significant extent.

It is intended to publish a full account of this work elsewhere.

Preservation of Grass for Winter-feeding by Radiation Sterilization

IN the course of investigations on microbial decomposition of grass carried out at Hurley by one of us (E. G.), a method of sterilization was sought which would not alter appreciably the chemical and physical structure of grass. Ionizing radiation gave the most promising results. It was then decided to explore the possibilities of preserving grass for winter-feeding on a purely experimental basis by this method. A preliminary account by Grossbard *et al.*[1] was published in 1957. Radiation sterilization of meat, dairy products, grain and other materials has been studied extensively. The results have been reviewed by Hannan[2], Comar[3] and others.

Irradiation of small experimental samples (50–100 gm.) of ryegrass (*Lolium perenne*) tightly packed in cylindrical containers of polystyrene were carried out at the Wantage Radiation Laboratory. A cobalt-60 source was used and dosages of 1×10^6 to 4×10^6 rads were applied. Extensive sterility tests showed that a dose of 2×10^6 rads $\pm$ 10 per cent was adequate for complete sterilization. This agrees with the findings of other workers using different biological materials.

The samples were stored for periods of 6–18 months. Irradiation in itself did not cause any conspicuous changes in the physical appearance of the grass. However, a characteristic though not unpleasant odour developed immediately after irradiation. Samples kept in the dark at 4° C. retained their green colour up to six months, while those stored in the light at laboratory temperatures turned a straw colour after two to three months. Possibly factors other than temperature and light will affect persistence of chlorophyll.

Recently, exploratory experiments were carried out on larger samples ranging from 500 to 2,000 gm. tightly packed in polyethylene bags or tinned cans. A total of 30–40 kgm. was irradiated at any one time either from a cobalt-60 source or a 4-MeV. linear accelerator. The results obtained using the accelerator were inconsistent in themselves owing to the difficulty of measuring the dose delivered to the grass.

Batches of this irradiated grass were then fed to experimental sheep. A total of six animals was used for this test. Whether this grass was fed immediately following irradiation or after a month of storage the sheep soon became accustomed to it. While our results are of necessity on a small scale, it appears that irradiation in itself does not interfere appreciably with the palatability of the grass.

It is intended to irradiate larger bales of grass in the spent fuel-rod assembly at the Atomic Energy Research Establishment, Harwell, and to carry out more extensive trials on palatability, digestibility and the nutritional value of irradiated grass.

Another problem which is under investigation is a suitable container in which to pack and store the grass. We find that in polyethylene bags recontamination readily occurs, possibly owing to changes which have taken place in the plastic as a result of irradiation. Small sample bags of 'Metathene' (a polyethylene-'Cellophane' laminated film produced by the Metal Box Co.) filled with grass and placed inside the polyethylene bags also containing grass were more resistant, and while recontamination occurred on storage the percentage was lower than in polyethylene bags. So far the tin cans proved to be the most suitable containers.

We wish to thank Mr. W. F. Raymond for his interest in this work and Mr. G. E. Outen for valuable technical assistance.

Polarization of Light of the Comets Arend-Roland (1956*h*) and Mrkos (1957*d*)

POLARIZATION of the total light of the Comets 1956*h* and 1957*d* was studied photographically by simultaneous exposures with three objectives and three 'Polaroids'. The planes of polarization of the three 'Polaroids' were at 120°. 2-in. objectives were used at $f/9$ with Agfa 'Astro' panchromatic plates. The characteristic curve was determined by comparison with an exposed photometric wedge. Errors due to the instrument were measured by means of light from an artificial source, polarized to a known degree by reflexion from a glass surface. The error of the polarization determined is $\pm 2 \cdot 5$ per cent.

Altogether we obtained seven plates of the Comet 1956*h*, during April 27–May 29, 1957. Only five of them, however, were suitable for detailed measurement. The Comet 1957*d* was photographed three times, but only two of these plates, during August 20–23, 1957, were measured. This was done with a self-recording microphotometer, using a square slit with an area of $0 \cdot 005$ mm.^{2}. In the case of the Comet 1957*h*, where the phase-angle θ was 58° or 69°, respectively, the values found were reduced for $\theta = 90°$. The results of our measurements are shown in Tables 1 and 2.

Table 1. Degree of Polarization (per cent) of the Light from Comet Arend-Roland 1956*h*

Date (1957)	Phase angle, θ	Distance from the head (min. of arc)								
		3	4	5	6	8	10	12	14	16
April 27	98	18·9	22·4	23·5	23·2					
,, 27	98	21·7	21·9	23·4	23·8	26·6	27·1			
,, 29	92	11·2	14·9	15·2	17·4	18·5				
May 1	85	11·9	15·1	17·2	15·2	20·7				
,, 2	81		12·8		15·7	18·2	17·5	19·1	18·9	19·2

Table 2. Degree of Polarization (per cent) of the Light from Comet Mrkos 1957*d*

Date (1957)	Phase angle (θ)	Distance from the head (min. of arc)				
		3	4	5	6	8
August 20	63	10·8	10·5	10·5	10·8	
,, 23	59·5	10·8	8·2	8·4	7·7	10·9
		For phase angle θ = 90°				
,, 20		14·1	13·7	13·7	14·1	
,, 23		15·1	11·3	11·6	10·7	15·3

Using these results, we came to the following conclusions: (1) The degree of polarization in the tail of the Comet 1956*h* decreases towards the head, but is fairly constant at large distances from the coma. (2) There was a sudden decrease of the degree of polarization in the whole tail of the Comet 1956*h* between April 27 and 29. (3) The degree of polarization in the tail of the Comet 1956*h* agrees with values found by other observers[1–3], though that of Barber[4] is extremely high compared to ours. (4) The degree of polarization in the tail of the Comet 1957*d* is distinctly lower. In contradiction to the results of Barber[4], the polarization of light from this comet may be explained as predominantly due to pure molecular emission. On the other hand, the higher values found for Comet 1956*h* may be explained by an increased proportion of light scattered by dust particles. This also agrees with the published spectrographic results, which indicate that the continuous spectrum was also extraordinarily prominent in Comet 1956*h*. The colour index, measured by Tremko and Vanýsek[5], was found to be + 0·59 in the *BV* system for the Comet 1956*h*, very close to the colour index of the Sun, but it was as low as + 0·19 in the light of Comet 1957*d*.

Correlation of Whistlers and Lightning Flashes by Direct Aural and Visual Observation

Extending the theoretical work of Eckersley[1], and combining it with extensive experimental observations, Storey• deduced that whistlers result from the energy of very low frequency radiated by lightning flashes, propagated up to great heights along the flux of the Earth's magnetic field and down again to the ground at the geomagnetically symmetrical place in the opposite hemisphere, taking a second or two to make this very long trip. The lower frequencies travel more slowly than the high, so that the original impulse is spread out into a swish or whistler of descending pitch when it is received[2].

Allcock and I have reported that the simultaneous observation of whistlers at conjugate points in the northern and southern hemispheres bears out the essential details of Storey's hypothesis, and Helliwell and Gehrels have found that very low-frequency broadcast signals can be received in the opposite hemisphere after propagation in the whistler mode[3].

Helliwell, Gallet and Ellis have each noted independently that, above a certain frequency, the dispersion must reverse. This was first verified by Helliwell[4,5].

Throughout this development, there has remained the disquieting fact that nearly all known attempts to observe lightning by visual perception and to hear a resulting whistler have been unsuccessful. Eckersley reported that "K. Tremellen has found that Isolated Whistlers are definitely caused at certain times by local lightning flashes"; and Dinger and I have communicated an observation by A. G. Jean[1,6]. Because these reports have not been sufficiently elucidated, or readily duplicated, there have been persistent suggestions that whistlers may not be generated by lightning.

In 1957, on May 27 at about 0215 *Z* at Hanover, N.H., I noted a distant lightning flash in the night sky. Turning to a whistler receiver I heard almost continuous whistler activity. The whistlers were the long or round-trip type, followed by echo trains. Their intensity was not great, and it was not possible at that time to detect any correspondence with the visible lightning flashes which were continuing. In time, the storm producing the flashes came closer until thunder could be heard. By then, I observed that some flashes were producing weak whistlers, but the majority still were not. As the storm continued its advance, the flashes became less frequent and the resulting 'sferics' became noticeably shorter in duration and greater in intensity (by aural perception). By about 0500 *Z*, every visible flash was producing a strong whistler with several echoes and there were no other whistlers present. Flashes were occurring about three minutes apart and there were no other 'sferics' present except a steady barrage of very weak tweeks.

This situation persisted for about an hour, after which the flashes became still less frequent and I finally saw no more. Coincidentally I heard no more whistlers. Throughout, the clouds hung low and there was much mist near the ground. Heavy rain fell at times. Although the flashes lit up the countryside, I could not see the discharge paths from my position.

From this successful observation, and many unsuccessful ones of the past, it is concluded:

(1) that lightning flashes can generate whistlers, (2) that most lightning flashes do not generate whistlers.

A Simple Device for observing the Polarization of Light from the Sky

Chapman[1] has recently described a device for visualizing the pattern of plane-polarized light from blue sky, which seems to be unnecessarily complicated and expensive.

The ability of certain animals to perceive the polarization of light is not entirely absent in man. In the human eye polarized light causes an 'entoptic' phenomenon called Haidinger's brushes. This consists of two yellow sheaves radiating in opposite directions from the point of fixation. The sheaves are flanked by blue hyperbolic regions. The axis of the blue hyperbola corresponds to the plane of vibration of the electric vector of linearly polarized light, which is at right angles to the 'plane of polarization'. It is quite easy to see Haidinger's brushes by rotating a polarizer slowly before the eye, but to use the phenomenon to study the polarization of the light from the sky is difficult as the percentage of polarized light is never very large. After some training it is, however, often possible.

A simple sky-compass was constructed by Tschermak-Seysenegg[2] from a rectangular piece of 'Polaroid' with the optical axis parallel to one of the sides of the rectangle. From this are cut out (as shown in Fig. 1) 12 isosceles triangles with their bases parallel to the long side of the rectangle and with their top angles 30°. These triangles are then arranged to a regular dodecagon. If one looks at the sky through this 'radial analyser' light and dark sectors are seen, as with Chapman's device.

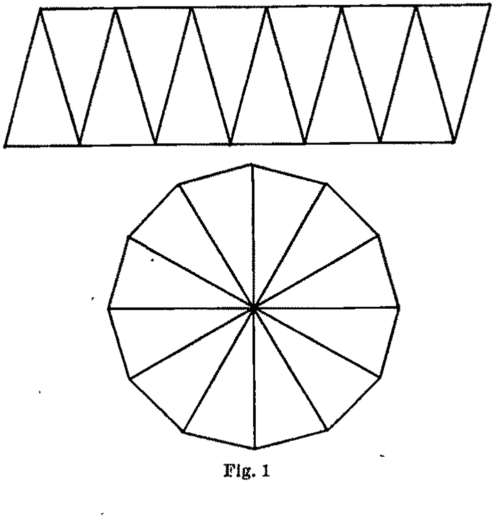

Fig. 1

The sensitivity of this simple apparatus is increased by combining the 'radial analyser' with a 'radial retarding plate'. I have used 'Cellophane'[3] as the birefringent material. Double layers of 'Cellophane' are pasted on a piece of 'Polaroid'. The optical axis of the tape (which is parallel to the fine striation of the material) is kept at 45° to that of the 'Polaroid'. The whole is then cut into triangles and arranged to form a dodecagon as above. In this way the sectors appear yellowish-green and purple and are easy to observe even if the percentage of polarized light is small.

Verdet Constants of Rare-Earth Glasses measured with a New Polarimeter

In some optical devices the Faraday effect is used with advantage as a shutter, and, as a modulator of a light beam, it is especially useful in polarimetry[1–3]. In such applications a material having a large value of the Verdet constant is usually sought, consistent with adequate transmission at the desired wavelengths. While numerous materials, especially thin metal films and ferrites, are known which have large absolute values of the Verdet constant[4], measurements reported here are limited to glasses.

From the data published by Cole[5] the Verdet constants of silicate glasses not containing rare-earths are seen to be approximately proportional to the reciprocal of their constringence, and positive. Therefore, a low-power magneto-optic modulator using the Faraday effect has often depended upon the use of a dense flint glass of low constringence.

It was discovered here that there is at least one readily available glass the Verdet constant of which is negative : didymium filter glass, type *ON*16 (Chance-Pilkington Optical Works, Ltd.). The negative Verdet constant of this glass raised the question of how the Verdet constant would depend upon the presence of a paramagnetic rare-earth in a glass.

A preliminary examination with a visual polarimeter of some experimental glasses, obtained from the research laboratories of Messrs. Pilkington Brothers, Ltd., was then made. These glasses contained a constant proportion of boric oxide, and samarium oxide replacing lanthanum oxide from 0 to 65 per cent by weight. It was found that their Verdet constants, while positive in sign, decreased with increasing samarium content.

Finally, the Verdet constants of a number of borate glasses specially made by the above Research Laboratories and containing graded proportions of the paramagnetic rare-earths gadolinium and dysprosium were measured using the recently available *ETL-NPL* automatic polarimeter.

The operation of this polarimeter has been described elsewhere[6], but it should be noted that the activity of a sample in this polarimeter appears as an analogue electric current. In these experiments this current was measured using an adjustable shunt and a potentiometric chart recorder.

The optical activity was measured using an incandescent source filtered in the neighbourhood of mercury green with a half-intensity width of 200 A. A reduced aperture was used so that the beam crossing the sample had a diameter of 2 mm.

The various samples were polished plane-parallel to thicknesses between 2 and 3 mm., and were left as fragments of less than $\frac{5}{8}$ in. in any other dimension.

An axial magnetic field of about 1,120 gauss was provided in a sample holder which used two axially polarized permanent magnets of an annular shape. The flux path of each magnet was nearly completed with turned soft-iron washers having a conical inside surface perforated with a central $\frac{1}{8}$-in. hole, and leaving an axial gap of $\frac{1}{8}$ in. to contain the sample. Two such assemblies with their magnetic fields in opposition were mounted within a plastic holder having an outside diameter of 30 mm. Only one magnet assembly was used to contain the sample, and the magnetic fields of the two tended to cancel, so that the effect of stray magnetic fields upon the polarimeter was reduced to less than 0·008° arc and could be corrected for. During the course of some fifty measurements where the sample holder was dismantled and re-assembled each time, the effective field-strength H was found to have decayed by less than 1 per cent.

The effective field-strength H in the perforated gap of the sample holder can be found by referring the observed magneto-optic rotation of fused quartz α_q to the known Verdet constant V_q of fused quartz[7] (16·64 min./kilogilbert):

$$H = \alpha_q / V_q p_q \qquad (1)$$

where p_q is the path-length. Measurements of the Verdet constants of the rare-earth glasses were then made referring to the Verdet constant of fused quartz. Thus, if the observed sample rotation α_s in a path-length p_s corresponds to a sample Verdet constant V_s:

$$V_s = \alpha_s / H_s p_s \qquad (2)$$

Upon substituting the value of H from (1) then,

$$V_s = V_q(\alpha_s/\alpha_q)\ (p_q/p_s) \qquad (3)$$

Chart records of the optical activity of the fused quartz reference and of the sample glasses were usually made alternately, and the ratios of optical activity taken from adjacent traces. The chart record was also convenient in observing the birefringence of the samples, as an oscillatory trace was obtained when the sample holder, together with the sample in it, was slowly turned about the optical axis. The activity of the sample was then taken as the average value of the trace over at least four cycles.

In all cases the birefringence greatly exceeded the inherent noise-level of the instrument, which was 0·001° arc in a 1 c./s. bandpass. The total excursion of the recorder trace due to residual birefringence is recorded in Table 1 as per cent of the mean optical activity.

The Verdet constants of the six new rare-earth glasses are listed in Table 1. The six samples all contained 37·5 per cent by weight boric oxide, and the balance both lanthanum and the paramagnetic rare-earth oxide.

For the comparison, the Verdet constant of a didymium filter glass, and the most dense flint glass available for construction of a Faraday cell, are included in Table 1.

Table 1

Glass	V_s (min./kilogilbert) λ = 546 nm.	Mean deviation (per cent)	Amplitude of birefringence (per cent)
Didymium *ON* 16	−25·3	1·2	18·0
10 wt. per cent Gd_2O_3	21·2	5·6	43·0
20 ,, ,, ,,	20·5	4·6	64·0
30 ,, ,, ,,	19·8	2·2	25·2
10 ,, ,, Dy_2O_3	−35·2	3·7	22·0
20 ,, ,, ,,	−93·8	3·0	12·8
30 ,, ,, ,,	−150·0	2·7	6·7
030181	151·0	—	—

These results show that certain glasses can have negative Verdet constants comparable in magnitude with that of the densest flint glasses.

It would be interesting to find out in more detail just how the presence of the paramagnetic rare-earth ion is related to the Verdet constant, and whether much greater Verdet constants could be obtained.

I am indebted to Mr. J. Kowal for making many of the measurements reported here, and to the Controller of Research, Dr. J. H. Mitchell, for permission to publish this paper.

Ordering in Liquid Mercury–Thallium Alloys containing 25–35 Atomic per cent Thallium

Recent X-ray measurements on liquid mercury–thallium alloys have given some evidence for ordering at compositions corresponding approximately to the solid-state compound Hg_5Tl_2 [1]. These results, obtained at 17° C., some 3° C. above the melting point of Hg_5Tl_2, are unfortunately inconclusive due to the uncertainty introduced by the extensive corrections necessary in the analysis of diffraction data. In the present work, evidence for the existence of ordering has been obtained by accurate determinations of the partial molar entropy of thallium, S^M_{Tl}.

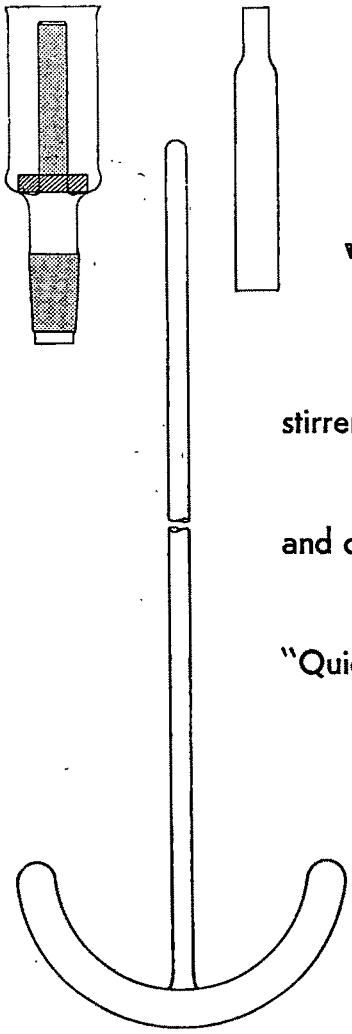
Measurements of electromotive force have been made on cells of the type:

$$Tl_{(cry.t.)}/TlSO_{4(aq.)}/Hg\text{–}Tl_{(liq.)}$$

between 10° and 90° C. for nine alloy compositions. The e.m.f.'s of all cells varied in the same general way with temperature, and the results with three representative alloys are shown in Fig. 1. Duplicate measurements on identical cells showed that the reproducibility over the range 20–35° C. was better than ± 0·02 mV. Confidence is felt in these results, as the calculated partial molar heats of solution of thallium agree to within 7 per cent with accepted direct calorimetric determinations[2,5].

The partial molar entropy of thallium, S^M_{Tl}, is calculated using the standard relation:

$$S^M_{Tl} = nF\left(\frac{\partial E}{\partial T}\right)_{N,P}$$



QUICKFIT

A new "Quickfit" Stirrer

The parallel ground sleeve stirrer gland is excellent for use under vacuum. It operates up to 700 revs a minute and only glass parts reach material handled. Can be used with all standard "Quickfit" stirrers and stirrer guides, including "anchor" stirrer for viscous materials.

Write for Supplement No. 4 giving full details.

and S^M_{Tl} for the range 20–35° C. is given in Fig. 2. The e.m.f. values above 50° C. were much less reproducible, and the error introduced into the S^M_{Tl} values in this range renders them valueless for the present purpose.

The variation of S^M_{Tl} with composition in the range 20–35° C., Fig. 2, is characteristic of solutions showing short-range order[3,4], and confirms the earlier inconclusive evidence for ordering from X-ray measurements[1]. This effect was not noticed by previous workers[5], who used more widely spaced compositions. For an ideal random solution this plot would be linear with gradient $-R$, but short-range ordering introduces a deviation to lower entropies at concentrations below the ordering composition, and a symmetrical swing to higher entropies at higher concentrations[3,4]. The 'cross-over' composition at 29·4 atomic per cent thallium indicates that ordering occurs at the composition $Hg_{12}Tl_5$; this formula could equally well be assigned to the solid-state compound for which Hg_5Tl_2 (28·6 atomic per cent thallium) was originally proposed, as both compositions fall within the limits of accuracy of the equilibrium phase determinations[6].

The change in entropy in the ordering region (27–32 atomic per cent thallium) is quite small (± 0·3 J.E.U.), indicating rather feeble ordering, which would account for the difficulty in detecting ordering in the diffraction studies[1]. The low heat of formation of the solid alloy[7] of − 0·35 kcal./gm.-atom also suggests a feeble tendency to compound formation.

The increasing gradient of the e.m.f. vs. temperature plots (Fig. 1) between 35° and 50° C. indicates an increase in the entropy of thallium which may reasonably be interpreted as an increase in atomic randomness over this temperature-range. This occurs at all alloy compositions, and approximate entropy values from the upper slopes of the curves indicate that complete randomness is not attained; it seems likely that the change is one of co-ordination. Accurate entropy values above 50° C. are necessary to clarify this position, and attempts are now being made to obtain stable reproducible e.m.f.'s between 50° and 90° C.

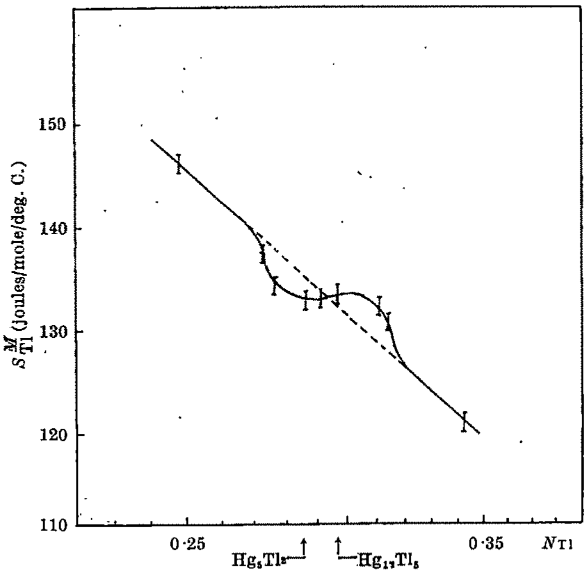

Fig. 2. Partial molar entropy of solution of thallium (S^M_{Tl}) vs. log composition (mole fraction thallium) at 20° C. The estimated errors in the experimental points are indicated

Low-Angle X-Ray Scattering by Glasses

THERE have been reports on the discovery of low-angle X-ray scattering by glasses, and evidence has also been presented to the contrary[1–4]. In trying to produce low-angle X-ray scattering by various types of glasses it became apparent to us that spurious effects might arise when using powder samples, owing to the surface scattering by the grains of the ground glass. This consideration also made us doubt the results of Hoffman and Statton[3].

In our further attempts to obtain low-angle X-ray scattering we used polished glass plates, about 0·2 mm. in thickness. Complete absence of any surface effects was ensured by varying the thickness of the samples. The X-ray exposure was carried out in an evacuated chamber with Kratky collimation[5]. Filtered copper K_α-radiation was used with a sample-to-film distance of 350 mm.

We succeeded in producing a clear and reproducible low-angle X-ray scattering pattern for a series of samples of glass containing 7 per cent of sodium oxide, 23 per cent of boron oxide (B_2O_3) and 70 per cent of silicon (in mole per cent) ('Vicor' glass) heated at 600° and 650° for various time intervals (1–8 hr.) and quenched in air (Fig. 1). The initial sample was annealed at 500°. The intensity of the scattered light was also measured and found to increase with temperature and duration of heat treatment. At the same time, we obtained low-angle X-ray scattering by porous glasses produced by leaching the same samples (dotted curves in Fig. 1). Calculation has shown that the radii of the inhomogeneities in the initial glasses and the pore radii in the leached samples are very nearly the same, varying from about 100 A. for an original sample to about 900 A. for a sample heated at 650° for 6 hr. The corresponding increase in the intensity of scattered light is greater than 1,000 times.

Thus we have direct evidence for a chemically inhomogeneous structure in certain sodium borosilicate glasses. This evidence is strengthened by the similar size of the inhomogeneities artificially produced in the same glasses by leaching. (Some discrepancies between the dotted and full lines in Fig. 1 for samples 5 and 6 may be explained in terms of different operating conditions for the X-ray tube during the exposure of the glasses mentioned, namely, 30 kV. for the original and 15 kV. for the porous glasses.)

The observed intensity of the low-angle X-ray scattering is very low. Indeed, whereas porous glasses require exposure times of the order of several minutes, many scores of hours are needed when examining the original glasses. The reason lies in a very small difference between the electron densities in the chemically inhomogeneous regions. For the glasses investigated, this difference, calculated from the electron density of vitreous silica and the ratio of X-ray intensities scattered by the original and the porous glasses, is only about 0·04 electron/A. This explains why the attempts at producing low-angle X-ray scattering by other types of glasses have failed. These would also have considerably smaller inhomogeneities (if there were any at all), which would greatly increase the exposure time required. For example, an exposure of more than 2,000 hr. would be required with our apparatus to produce scattering by the same 'Vicor' glass with an inhomogeneity size of 50 A. To reveal such small chemical inhomogeneities considerably more sensitive apparatus should be used.

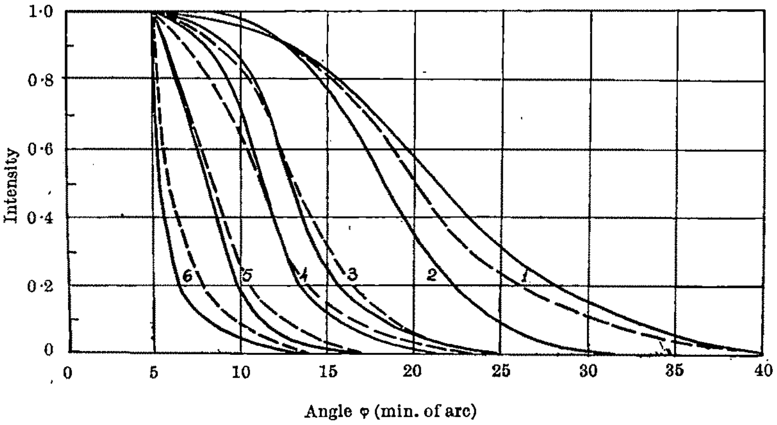

Fig. 1. Low-angle X-ray scattering intensity curves for original (——) and porous (– – –) glasses obtained by heat treatment of the original glasses as follows (relative intensities of light scattering are shown in brackets): 1, 500° (1); 2, 600° for 2 hr.; 3, 600° for 4 hr.; 4, 600° for 8 hr. (3·4); 5, 650° for 1 hr. (30); 6, 650° for 6 hr. (> 1,000)

Emission and Absorption Spectra of NCO and NCS

Several polyatomic free radical spectra have been observed in fluorescence when various compounds are irradiated with Schumann ultra-violet radiation. Neuimin and Terenin[1] observed the spectrum of NH_2 in emission with this technique, and Style and co-workers have reported several fluorescence spectra which they have assigned to HCO (ref. 2), HCOO (ref. 3), CH_3O (ref. 4) and C_2H_5O (ref. 4).

A few years ago, two of us (R. H. and D. W. G. S.) observed a series of bands in the region 4250–4650 A. in the fluorescence from ethyl *iso*cyanate (C_2H_5NCO). The bands were also observed in emission from a high-frequency discharge through this compound at a pressure of about 1 mm. mercury. A reproduction of the bands excited by this latter technique is given in Fig. 1*a*. The principal feature is a group of strong bands in the region of 4400 A. A similar, but much weaker, group lies 1,275 cm.$^{-1}$ to lower frequencies of the main group. With both methyl thiocyanate (CH_3SCN) and methyl *iso*thiocyanate a series of ten bands in the region 3750–4850 A., together with a few weaker and less widely spaced bands at shorter wave-lengths, were obtained as a fluorescence, as shown in Fig. 1*b* and *c*. These bands were also readily obtained from the discharge through methyl thiocyanate. The interval of about 700 cm.$^{-1}$ is prominent.

Although the dispersion was insufficient to resolve the rotational fine structure, the fact that identical fluorescences were given by thiocyanate and *iso*thiocyanate suggested that the NCS radical was the emitter of these bands, and that those given by ethyl *iso*cyanate were due to NCO.

Since the energy of the ultra-violet radiation used for excitation in the fluorescence experiments is limited to about 9 eV. by the transmission limit of the fluorite windows, and since this energy is used to dissociate the parent molecule and to produce one of the dissociation products in an excited state, it is clear that the lower state of the emitter can only be the ground-state or a very low lying excited state. In the former case it

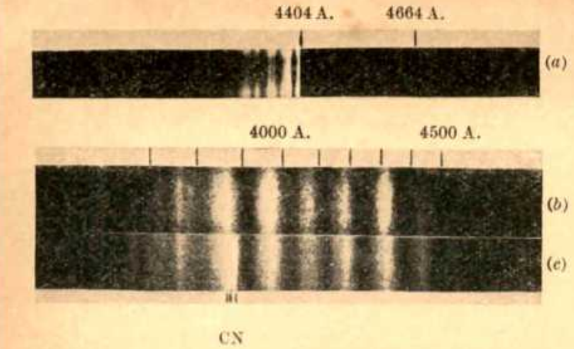

Fig. 1. Emission spectra of NCO and NCS. *a*, High-frequency discharge through C_2H_5NCO, glass spectrograph ; *b*, *c*, fluorescence from CH_3NCS and CH_3SCN, respectively, quartz spectrograph

should be possible to observe the spectrum in absorption.

Experiments were therefore carried out at Ottawa on the flash photolysis of the above compounds in an attempt to obtain these new spectra in absorption. The apparatus was similar to the one described earlier[5]. Four photolysis lamps were used, each being fired by a 33-μF. condenser charged to 7 kV. The reaction cell was 50 cm. long and multiple reflexion mirrors were used to increase the optical path-length to 10 m. The spectra were photographed using a 21-ft. concave grating spectrograph.

During the flash photolysis of ethyl *iso*cyanate at 5 mm. pressure several violet degraded bands were observed in absorption in the region 3600–4500 A. ; in addition, seven red degraded bands were observed between 2620 and 3160 A. The bands were observed with increased intensity during the flash photolysis of *iso*cyanic acid, HNCO. The strongest violet degraded absorption band is reproduced in Fig. 2*a* and corresponds to the strongest band observed in emission (Fig. 1*a*). A typical red degraded band is shown in Fig. 2*b*. A rotational and vibrational analysis of several of the violet degraded bands has been carried out and shows that the bands belong to a $^2\Sigma$—$^2\Pi_i(a)$ electronic transition of a linear molecule. The rotational constants are $B'_{000} = 0{\cdot}402_1$ cm.$^{-1}$ and $B''_{000} = 0{\cdot}389_4$ cm.$^{-1}$ and are consistent with the assignment of the carrier to the NCO radical. The red degraded bands belong to a second electronic transition which appears to be of the type $^2\Pi_i(a)$–$^2\Pi_i(a)$. The two band systems are thus analogous to the well-known band systems[6,7] of the isoelectronic molecule CO_2^+, except that the order of the excited states is reversed.

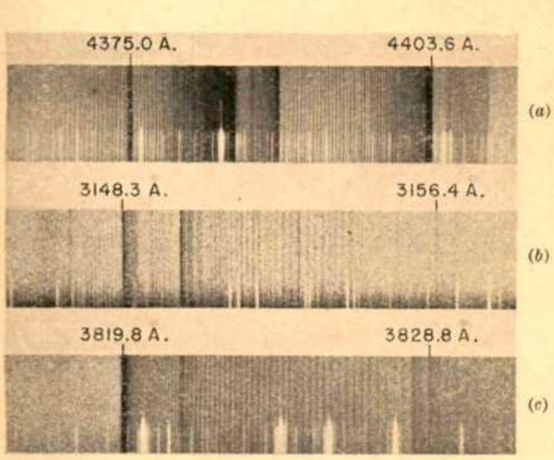

Fig. 2. Absorption bands of NCO and NCS photographed with a 21-ft. grating spectrograph during flash photolysis experiments : *a*, strongest band of the violet degraded system of NCO from HNCO ; *b*, a typical band of the red degraded system of NCO from HNCO ; *c*, a typical sub-band of NCS from CH_3SCN (diluted with argon)

Another series of red degraded bands was observed in the region 3350–4000 A. during the flash photolysis of methyl and ethyl thiocyanates and ethyl *iso*thiocyanate. Two of the bands with heads at 3712 and 3820 A. correspond to two of the emission bands shown in Figs. 1*b* and 1*c*. Under high resolution the rotational structures of these bands correspond to $^2\Pi_i(a)$–$^2\Pi(a)$ bands of a linear molecule with large sub-band spacings. One of these sub-bands is reproduced in Fig. 2*c*. The bands are similar to the corresponding bands of NCO and may be assigned to the NCS radical.

From the methods of production of these spectra and from the rotational fine structures of the bands there can be little doubt of the assignment of the spectra to the NCO and NCS free radicals. Detailed rotational and vibrational analyses are being carried out at Ottawa and will be published in due course.

Cadmium Bromide : Growth Spirals and Possible Polytypism

IN recent years growth spirals have been observed on crystals of nearly thirty[1] substances. Detailed descriptions of these markings, as well as their relationship to screw dislocations, have been given especially of crystals of silicon carbide[1,2] and cadmium iodide[3]. I wish to report the occurrence of growth spirals on crystals of cadmium bromide ($CdBr_2$), and to comment on their implications regarding possible structural polytypism in this compound.

Numerous spiral markings have been observed on the (0001) faces of cadmium bromide crystals. These crystals, which measure approximately 0·2 mm. across, were grown from an aqueous solution of cadmium bromide, reagent grade ($CdBr_2.4H_2O$), to which a liberal amount of hydrobromic acid had been added. For the most part the markings are circular with a slight suggestion of hexagonal or triagonal shape. Both left- and right-handed spirals occur. Single spirals are present, but combinations and intergrowths of spirals are more common. Fig. 1*A* shows a marking produced by three screw dislocations of the same sign, sufficiently close together

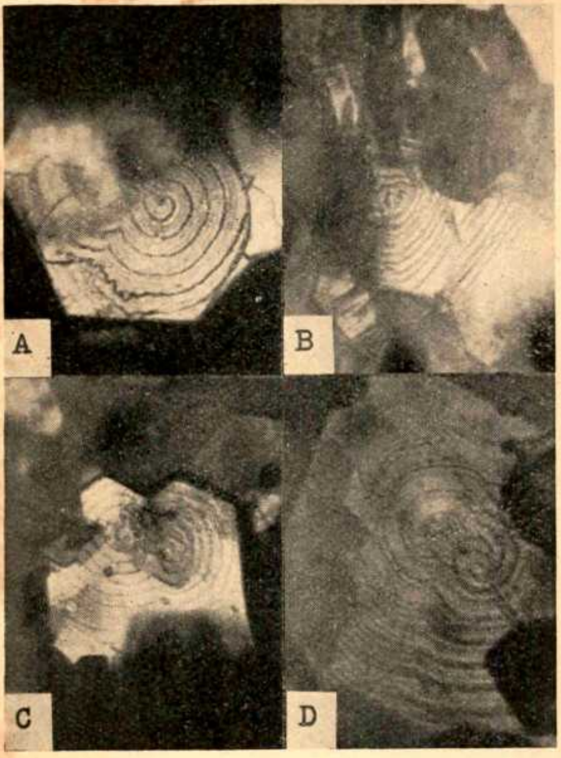

Fig. 1. Photomicrographs of growth spirals on crystals of cadmium bromide ($CdBr_2$). Vertically reflected light. (× 216)

for co-operation with one another. The Burgers vector of one of the dislocations is greater than the other two, thus producing the more prominent spiral step. More complicated patterns were seen in which the distance of separation of the dislocations was greater. Frequently one observes spirals formed from two or more dislocations of opposite sign. Fig. 1*B* shows a case where two dislocations of opposite sign, and of the same Burgers vector, have interacted to form closed triangular loops. Fig. 1*C* illustrates a case where two spirals of opposite sign and some distance apart interacted with each other. This looks like a case in which two crystals have joined and then grown. Many other more complicated cases were observed in which dislocations of the same and opposite signs and different Burgers vectors result in interacting spiral markings (Fig. 1*D*).

Recent studies have shown a relationship between structural polytypism and the spiral growth of crystals resulting from screw dislocations in silicon carbide[4] and cadmium iodide[5] structures. From a knowledge of these studies, I propose that a series of polytypic structures may also exist for cadmium bromide. Normal cadmium bromide, designated as $6R$ by Ramsdell's[6] notation, has an ideal structure represented by $[(A\gamma B)\ (C\beta A)\ (B\alpha C)]_n$, in which bromine ions are represented by Roman letters and cadmium ions by Greek letters in the common notation for the closest packing of spheres. The following structural series might be formed by various single dislocations in this ideal structure :

$2H$, $[(A\gamma B)]_n$
$6R$, $[(A\gamma B)(C\beta A)(B\alpha C)]_n$
$8H$, $[(A\gamma B)(C\beta A)(B\alpha C)(A\gamma B)]_n$
$6R$, $[(A\gamma B)(C\beta A)(B\alpha C)(A\gamma B)(C\beta A)(B\alpha C)]_n$
$14H$, $[(A\gamma B)(C\beta A)(B\alpha C)(A\gamma B)(C\beta A)(B\alpha C)(A\gamma B)]_n$
$6R$, $[(A\gamma B)(C\beta A)(B\alpha C)(A\gamma B)(C\beta A)(B\alpha C)(A\gamma B)(C\beta A)(B\alpha C)]_n$
$20H$, $[(A\gamma B)(C\beta A)(B\alpha C)(A\gamma B)(C\beta A)(B\alpha C)(A\gamma B)(C\beta A)(B\alpha C)$
$(A\gamma B)]_n$, etc.

Using the Ramsdell zigzag sequence[6] of bromine ions in the $(11\bar{2}0)$ cross-section, the hexagonal series could be represented by (1,1), (7,1), (13,1), (19,1) . . . ($n6 + 1,1$), where n is either zero or an integer. From a study of the geometry of the structure of cadmium bromide I have also conceived the possibility of less common dislocations producing a second series of polytypes :

$4H$, $[(A\gamma B)(C\alpha B)]_n$
$6R$, $[(A\gamma B)(C\beta A)(B\alpha C)]_n$
$10H$, $[(A\gamma B)(C\beta A)(B\alpha C)(A\gamma B)(C\alpha B)]_n$
$6R$, $[(A\gamma B)(C\beta A)(B\alpha C)(A\gamma B)(C\beta A)(B\alpha C)]_n$
$16H$, $[(A\gamma B)(C\beta A)(B\alpha C)(A\gamma B)(C\beta A)(B\alpha C)(A\gamma B)(C\alpha B)]_n$
$6R$, $[(A\gamma B)(C\beta A)(B\alpha C)(A\gamma B)(C\beta A)(B\alpha C)(A\gamma B)(C\beta A)(B\alpha C)]_n$
$22H$, $[(A\gamma B)(C\beta A)(B\alpha C)(A\gamma B)(C\beta A)(B\alpha C)(A\gamma B)(C\beta A)(B\alpha C)$
$(A\gamma B)(C\alpha B)]_n$, etc.

The zigzag sequence symbols for the hexagonal forms are : (2,2), (8,2), (14,2), (20,2) . . . ($n6 + 2,2$). In both these series the ideal structure $6R$ always results when the Burgers vector strength is a multiple of 6. Co-operating dislocations of mixed signs and Burgers vector strengths would, of course, generate other more complicated polytypic structures.

I am currently engaged in an X-ray study of this compound to ascertain if some of the predicted structures exist. I have verified the ideal structure and found the $4H$ form as well as strong evidence for other polytypes. In an earlier study, Pinsker[7] reported the existence of $2H$ and $4H$ forms. The results of the present X-ray study will be published in due course.

This work is being financed by a Research Corporation Frederick Gardner Cottrell grant.

Vacuum Arcs on Tungsten Cathodes

IN the course of a programme of work on direct-current arc discharges at low gas pressure an interesting phenomenon was encountered.

Photomicrographs of tungsten cathode surfaces were taken before and after an arc of 150 amp. had operated for about 30 msec. in air at 1μ of mercury. The arc was initiated by touching a pointed anode on to the cathode surface. Both electrodes were of tungsten rod, as used for inert electrode welding. This material was later analysed spectroscopically and found to contain only trace impurities. The cathode surface shown in the illustrations was finished with grade 3–0 polishing paper.

Fig. 1*a* shows a ¼-in. diameter cathode, at a magnification of six times, before the arc occurred, and Figs. 1*b* and 2 show the same surface after arcing at magnifications of six and seven hundred respectively.

It can be seen that small areas of tungsten have been melted and the craters are distributed along fine cracks which were present before arcing.

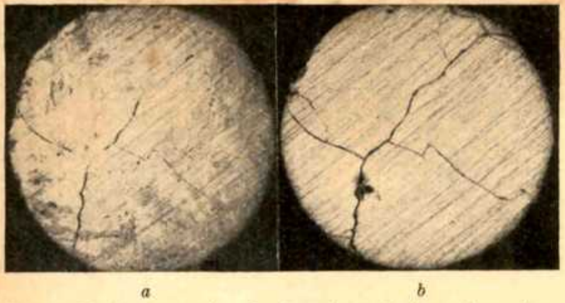

Fig. 1. Photomicrographs of a tungsten cathode surface. Arc current 150 amp., residual gas, air at 1μ mercury pressure, arc duration about 30 msec. *a*, Before arcing; *b*, after. (× 6.) The dark marking in the bottom left quadrant of *b* is the point of contact of the electrodes

Photomicrographs at high power (× 1,000) of the same section of the cathode surface, before and after arcing, show conclusively that melting occurs only on the cracks, when these exist. Results on specimens without cracks show isolated patches of overlapping craters, the surface in between appearing quite undisturbed—at least under visual observation at magnifications up to a thousand.

Other experiments, which will be reported in full elsewhere, indicate that vacuum arcs on both refractory and non-refractory cathodes behave like cold cathode arcs and have a small, mobile cathode spot region. Using a fine crack on a tungsten cathode to 'guide' the cathode spot, attempts were made to photograph this region using high-speed ciné photographic techniques. The experiments were unsuccessful. It is considered quite possible that the cathode spot does not move along the track at all, but has a random motion and only melts the tungsten when it crosses the sharp edge of a crack.

The melting is never continuous, although simultaneous oscillograms show the arc voltage to be continuous, though fluctuating.

The craters are very small in area, for example, some of those shown in Fig. 2 are about a micron in radius, giving an area of only about 3×10^{-8} cm.^{2}, Now, although the total arc current is 150 amp.. 'spot splitting' occurs, that is, there are many small cathode spots active, 'in parallel'. Thus the current associated with each crater is not known, but it is considered that it is at least 1 amp. and very probably more. Also, the actual area over which electron emission occurs may be greater than the melted area, but even when this is borne in mind, these results indicate an extremely high current density at the cathode. Values between 10^7 and 10^8 amp./cm.^{2} are by no means out of the question.

Tensile Strength of Indium

THIS communication presents new approximate values of tensile strength and percentage elongation for indium.

Most tabulations[1,2] of properties list the following mechanical properties for indium containing 0·29 per cent impurities:

Tensile strength	7·99 tons/in.^{2} or 17,900 lb./in.^{2}
Percentage elongation in 3 in.	26·5 per cent

These data were taken from the work of W. Chandler Roberts-Austen[3] in which he studied the effect of adding small amounts of impurity metals on the tensile strength of gold. In his table of data[3] is listed the above-mentioned properties for an alloy of gold containing 0·29 per cent indium, which has since been misinterpreted as applying to indium with a 0·29 per cent impurity. Upon discovery of this error, we undertook an investigation of the true properties of indium.

We had obtained a limited amount of indium (99·97+ per cent pure) from the Indium Corporation of America in connexion with other studies. This was cast into three tensile bars using heated graphite moulds. The size and shape of the bar is not standard (see Fig. 1), but was assumed to be satisfactory for the test, since similar bars cast of lead produced results comparable to the accepted values for that metal.

Standard tensile test machines are unsuitable for testing material of such low strength. To overcome this difficulty, a method was devised consisting of gradually filling a bucket, suspended by the tensile bar, with lead shot. This method has two distinct advantages, namely, adaptability to low loads and control of loading rate. The latter is very important when one recalls that soft materials such as indium creep at room temperature.

The conditions and results of the tests were as follows:

Bar No.	Diameter (in.)	Gauge length (in.)	Area (in.^{2})	Load (lb.)	Elongation (in.)	Tensile strength (lb./sq.in.)	Percentage elongation
1	0·369	0·78	0·1070	42·25	1·32	395	69
2	0·371	0·78	0·1080	38·75	1·32	359	69
3	0·370	0·78	0·1075	44·13	1·34	410	72
					Averages	388	70

Fig. 2 shows the pulled bars. A loading rate of 8·6 lb./min. was used in all tests. The average tensile strength of indium is approximately 388 lb./in.^{2} and the average elongation is approximately 70 per cent. Fig. 3 shows the nature of the fracture in the three bars (they are numbered from left to right as in Figs. 1 and 2). Bar No. 3, which had the highest values of tensile strength and elongation also has the expected type of fracture, showing almost 100 per cent reduction in area. This tends to indicate that the averages of 388 lb./in.^{2} and 70 per cent are on the

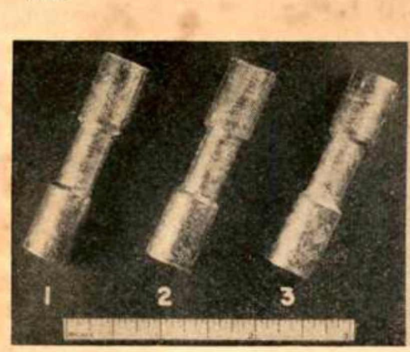

Fig. 1. Tensile bars as cast

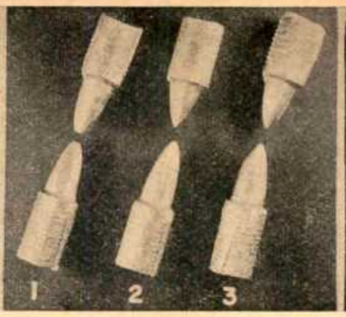

Fig. 2. Tensile bars after fracture

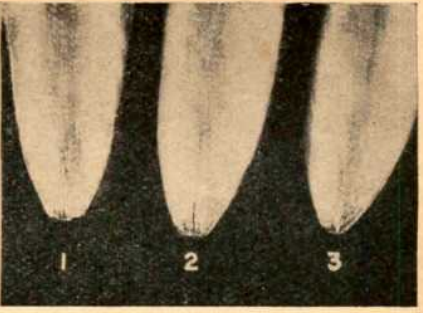

Fig. 3. Appearance of fractures

low side, probably due to imperfections in the cast bars.

Mass Spectrometry of Substances of Low Volatility

A LARGE range of substances which, because of their thermal instability or involatility, are unsuitable for admission in the gaseous state through a heated-inlet system into the ionization chamber of a mass spectrometer are usually studied by means of devices for volatilizing them very near the ionizing beam[1-6]. As a variant of the technique described by Bradt and Mohler[5], a Metropolitan-Vickers *M.S.*3 tube has been modified for the study of the effects of heat on coal and coal extracts in the temperature range 60–450° C.

The replacement of the original ion-source flange by one with additional electrical leads and an enlarged gas-inlet tube has made it possible to mount an electrically heated tubular furnace within 1 cm. of the entrance-port of the ionization chamber. The main differences from the apparatus of Bradt and Mohler are the following: (*a*) since the furnace has a heat capacity which is large compared with the sample holder, the thermocouple has been mounted in the furnace block; (*b*) the sample holder is mounted at the end of a glass rod extending up the gas-inlet tube in order that the whole unit may be moved in and out of the furnace magnetically by means of an iron bar sealed in the opposite end of the holder, thereby permitting out-gassing of the furnace, adjustments of temperature, and determinations of blanks; (*c*) the gas-inlet system remains connected to permit the introduction of mass-markers or to check the performance of the instrument under standard conditions.

The most satisfactory design of sample holder has been made from about 0·15 gm. of fine copper gauze rolled to form a cylinder which makes a good sliding fit inside the furnace tube. This is held on the probe by a small chuck, which also reduces the streaming of products back into the upper portion of the tube.

The normal procedure has been to study the growth and decay of the spectra at a succession of increasing temperatures. With the present vibrating reed electrometer and Sunvic *RSP*2 recorder (1 sec. full-scale deflexion) a scan of the mass region 53–215 can be made with reasonable accuracy in 6 min. This period is short compared with the life-time of the spectra produced by samples of 1–10 mgm. The amount of an individual substance released can be evaluated by time-integration of the height of a characteristic mass-peak because of the simple relation which exists between this integral and the sensitivity and leak-rate measured for the conventional inlet system.

Polystyrene was found to be a suitable material for testing the installation, and, as in the work of Bradt, Dibeler and Mohler[4], the monomer, dimer, trimer and tetramer were detected among the degradation products. For samples from different sources (for example, a commercial, catalyst-initiated polymer, a purified thermally initiated laboratory polymer, and an isotactic polymer) an interesting variation in behaviour has been observed with respect to the relatively small amount of decomposition which occurs in the temperature range 160–280° C. The details of a brief investigation of this phenomenon will be reported shortly.

A selection of coal vitrains is being studied by this technique. In addition to loosely bound aliphatic material with a wide range of molecular weight, a group of alkyl-substituted benzenes, naphthalenes and higher aromatics have been observed between 200° and 370° C. Above this temperature, where first traces of decomposition are signalled by the appearance of methane, corresponding series of substituted phenols and naphthols have been detected.

The instrument is also being used to characterize coal extracts and to estimate the distributions of molecular weights in various vacuum-distillation fractions.

Our thanks are due to the National Coal Board for the financial support of this investigation, further details of which will be published shortly.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

University Demonstrator (with an honours degree in chemistry or agricultural chemistry, and preferably a special interest in the problems of soil fertility) in Soil Science, for duties which will involve demonstrating in the whole field of soil science—The Secretary, School of Agriculture, The University, Cambridge (August 6).

Assistant in Zoology—The Secretary of the University Court, The University, Glasgow (August 8).

Laboratory Steward (over 21, previous experience in a biological, medical, biochemical or chemical laboratory, and preferably experience in the preparation of biological materials and photography) in the Department of Botany—The Registrar, University College, Singleton Park, Swansea (August 8).

Assistant Lecturer, Grade B, in Telecommunications and Electronics—The Clerk to the Governors, Woolwich Polytechnic, London, S.E.18 (August 9).

Assistant Lecturer in Inorganic and Structural Chemistry, and an Assistant Lecturer in Organic Chemistry—The Registrar, The University, Leeds 2 (August 9).

Lecturer in Physics, and a Lecturer in Bacteriology at the University of Adelaide, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, August 13).

Senior Lecturer or Lecturer (with a good honours degree and teaching experience) in Physics at the Nigerian College of Arts, Science and Technology—The Council for Overseas Colleges, 12 Lincoln's Inn Fields, London, W.C.2 (August 15).

Assistant Lecturer or Lecturer (preferably with some experience of structural analysis of organic and biomolecular compounds, and of the use of electronic digital machines) in Physics, with special reference to X-ray crystallography—The Secretary, Birkbeck College, Malet Street, London, W.C.1 (August 23).

Guinness Lecturer in Biochemical Engineering, to work in the Ramsay Memorial Laboratory of Chemical Engineering—The Secretary, University College, Gower Street, London, W.C.1 (September 1).

Assistant Lecturer in the Department of Geography—The Registrar, The University, Liverpool (September 6).

Reader in Fluid Mechanics at the Imperial College of Science and Technology—The Academic Registrar, University of London, Senate House, London, W.C.1 (September 11).

Associate Professor (with postgraduate experience of veterinary anatomy) of Veterinary Anatomy at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, September 15).

Reader, Senior Fellow or Fellow in the Department of Astronomy (Mount Stromlo Observatory), Research School of Physical Sciences, Australian National University, Canberra—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, September 15).

Senior Research Associate in Upper Atmospheric Physics, to carry out experimental and observational research on the airglow and auroræ—Prof. D. R. Bates, F.R.S., Department of Applied Mathematics, The Queen's University, Belfast (September 20).

Lecturer in Physiology at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, September 22).

Assistant Lecturer in Botany—The Registrar, The University, Manchester (September 30).

Lecturer (with a degree in veterinary science or in science with honours in comparative anatomy) in Veterinary Anatomy at the University of Queensland, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, September 30).

Lecturers (2) (with an honours degree in civil engineering and preferably with research or teaching experience in either hydraulics or soil mechanics) in Civil Engineering at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, September 30).

Lecturer or Senior Lecturer in Mathematics, and a Lecturer in Mathematics at the University of Tasmania, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, October 13).

Senior Research Officer or Research Officer (male, qualified zoologist with experience of fisheries research) in the Fisheries Research Unit, Department of Zoology, University of Hong Kong, The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Hong Kong, October 30).

Chair of Organic Chemistry in the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, October 31).

Assistant Lecturer (with a degree or diploma in horticulture) in Horticulture—The Registrar, Massey Agricultural College (University of New Zealand), Palmerston North, New Zealand.

Assistant Technical Editor (preferably between 20 and 30, with at least a pass degree in science, technology or arts) with the Ministry of Power in Sheffield, for work on reports and papers concerning safety in mines research—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.266/8A.

Biochemical Technician in the Physiology Department of the Medical School, to take charge of the preparation of material for biochemical classes for medical, dental and science students, and to assist if required in research work of a biochemical nature—Prof. A. A. Harper, Department of Physiology, Medical School, King's College (University of Durham), Newcastle-upon-Tyne 1.

Biochemist, Senior Scientific Officer or Scientific Officer grade (with considerable experience in the field of protein chemistry and/or tissue metabolism) in the Physiology Department, to take part in a programme of research on the biosynthesis of protein in the mammary gland—The Secretary, National Institute for Research in Dairying (University of Reading), Shinfield, Reading, Berks quoting Ref. 58/14.

Biochemist (with a degree in biochemistry, and preferably a Ph.D.), for full-time research on biological oxidation under Dr. V. Massey—The Secretary, Department of Biochemistry, The University, Sheffield 10.

Botanist (with a good honours degree and preferably some research experience, particularly in plant physiology), to join a small team engaged on studies of the constituents of natural rubber latex—The Director of Research, British Rubber Producers' Research Association, 48–56 Tewin Road, Welwyn Garden City, Herts.

Fish Biologist (with a good honours degree in natural science (zoology) and at least two years suitable postgraduate training or experience) at the Fish Culture Research Station, Malacca, Federation of Malaya, to study breeding, growth, feeding habits and life-history of fish of importance to fish culture—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.65/23/04.

Inorganic or Physical Chemists, Assistant Experimental Officer grade, at the Water Pollution Research Laboratory (D.S.I.R.), Stevenage, Herts, for work on physico-chemical problems in the study and prevention of pollution of rivers—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting Ref. F.479/8A.

Laboratory Technician (preferably with chemistry or physics experience equivalent to G.C.E. "A" level), for specialized work—The Secretary, Wright-Fleming Institute, St. Mary's Hospital, Paddington, London, W.2.

Lecturer (with a suitable degree and industrial or research experience, and preferably an interest in one of the following items: applications of X-ray crystallography, isotopes, statistics or fatigue) in the Department of Industrial Metallurgy—The Deputy Registrar, The University, Birmingham 15.

Postdoctoral Fellow in Inorganic or Organic Chemistry—The Chairman, Department of Chemistry, McGill University, Montreal, Canada.

Professors, Assistant Professors and Lecturers in Physics, Mathematics, Chemistry, Botany and Zoology at the University of Baghdad, Iraq—The Cultural Attaché, Embassy of the Arab Union, 22 Queen's Gate, London, S.W.7, or direct to Secretary-General, University of Baghdad, Iraq.

Research Scholars (with a first- or second-class honours degree, or the G.R.I.C.) in Chemistry, for work on the mechanisms of organic reactions and on organometallic compounds—The Registrar, The University, Leicester.

Scientific Officer or Senior Scientific Officer (with an honours degree and/or higher degree, and preferably a good knowledge of livestock and milk production), to develop current work on mastitis in relation to management—The Secretary, National Institute for Research in Dairying (University of Reading), Shinfield, Reading, quoting Ref. 58/20.

Senior Scientific Officer or Scientific Officer (with a first- or second-class honours degree or equivalent, several years experience in electronics or communications, and preferably also in airborne equipment design and pulse techniques), for duty at Orfordness, Suffolk, as a senior member of a team responsible for the design of air-borne telemetry equipment and associated ground stations, the organization and carrying out of flying trials on various types of weapons, and the analysis and evaluation of the results—The Senior Recruitment Officer, Atomic Weapons Research Establishment, Aldermaston, Berks, quoting Ref. 1845/34.

Student Technicians in the Department of Bacteriology and Pathological Museum—The Secretary, University College Hospital Medical School, University Street, London, W.C.1.

BINOCULAR MAGNIFIER X 10

7" WORKING CLEARANCE

At one setting a clear circular field of 22 mm. can be examined

Because of the enormous light gathering power (the object glasses are 30 mm. clear aperture), no special illumination system is required; the ordinary room lighting produces a brilliant image. The image is seen the right way round and the right way up so that no confusion occurs in manipulating objects in the field. Adjustment is provided for different eye separations and each eye-piece focuses separately, thus making allowance for any differences between the two eyes of the observer.

× 10 Binocular Magnifier with 1¼" Chromium plated column for fitting to customers' own special mounting. Complete in hardwood fitted case.
£44 10s. 0d.

Die Cast Arm with sleeve fitting to take plated column to screw on to a base or bench.

Scintillators in 5 forms

Scintillators in five forms are now available from Nash and Thompson Ltd.

CRYSTALS
Anthracene, Stilbene, Diphenylacetylene, in discs and cylinders.

PLASTICS
N.11 and N.11-X-ray, high sensitivity, high transmission polyvinyl toluene based.

LIQUIDS
Ready made, sealed in glass containers to your specification, or as scintipaks.

SCINTIPAKS
Accurately mixed dry constituents sealed in polythene envelopes, ready for dissolving in a suitable solvent as required.

POWDERS
Scintillation purity chemicals for crystal growing experiments, and the manufacture of special scintillators.

Meet Nash and Thompson on the S.I.M.A. Stand at the 'Atoms for Peace' Exhibition, Geneva, September 1st - 14th, 1958.

LECTURES AND COURSES

THE POLYTECHNIC

309 REGENT STREET, W.1

DEPARTMENT OF MATHEMATICS AND PHYSICS

The following courses of lectures have been arranged, starting in September, 1958:

1. MATHEMATICAL STATISTICS
   on Tuesday, Thursday and Friday evenings.
2. ADVANCED MATHEMATICS FOR SCIENTISTS AND ENGINEERS
   on Wednesday evenings.
3. MODERN ELECTRIC NETWORK THEORY
   on Friday evenings.
4. FINITE DIFFERENCE EQUATIONS AND DIFFERENCE-DIFFERENTIAL EQUATIONS
   on Monday evenings.
5. INTEGRAL EQUATIONS AND GREEN'S FUNCTIONS
   on Wednesday evenings.
6. AUTOMATIC DIGITAL COMPUTERS
   on Tuesday evenings.
7. ELECTRONICS
   on Monday, Wednesday and Thursday evenings.

Full particulars may be obtained on application to the Director of Education.

BIRKENHEAD EDUCATION COMMITTEE

BIRKENHEAD TECHNICAL COLLEGE SCIENCE DEPARTMENT

The following courses will be offered during the Session 1958-59.

Full-time Course, One Year, for Part II (Graduateship) R.I.C., commencing in October.

Evening Courses, Postgraduate (Visiting Specialist Lecturers)

(a) Chemistry of Co-ordination Compounds—Tuesdays, from October 14, 1958;

(b) Molecular Spectroscopy, both Practical and Theoretical—Mondays from October 6, 1958.

Further inquiries to the Head of Department of Science at the College. (Tel. No. Birkenhead 7337.)

H. GLYN WILKINSON,
Director of Education.

Education Offices,
63 Hamilton Square, Birkenhead.

BRUNEL COLLEGE OF TECHNOLOGY

WOODLANDS AVENUE, ACTON, W.3

Principal: J. Topping, M.Sc., Ph.D., D.I.C., F.Inst.P.

DEPARTMENT OF CHEMISTRY

Head of Department: J. H. Skellon, T.D., M.Sc., Ph.D., F.R.I.C.

SESSION OF 1958-9

FULL-TIME COURSES

Sandwich Courses in Applied Chemistry, Applied Biology, Metallurgy—for the Diploma in Technology or professional qualifications, commencing October, 1958 or January, 1959. Applications should be made immediately.

POSTGRADUATE AND HIGHER TECHNOLOGY COURSES

Lecture Courses

"Properties and Applications of Nickel Alloys at elevated temperatures." Six lectures on Thursdays at 7 p.m., commencing October 9, 1958.

"Gas Chromatography." Twelve Lectures on Wednesdays at 7 p.m., commencing September 24, 1958.

"Modern Methods of Instrumental Analysis Electrochemical analytical methods." Ten lectures and demonstrations on Thursdays at 6.30 p.m., commencing September 25, 1958.

"Ion Exchange Resins." Six lectures on Fridays at 7 p.m., commencing October 30, 1958.

Lecture and Laboratory Courses

"Radiochemistry Practice." Thirty sessions on Thursdays 2 to 9.30 p.m., commencing October 2, 1958.

"Some Aspects of Biochemistry." Thirty weeks on Fridays at 6.30 to 9.30 p.m., commencing September 26, 1958.

"Modern Chemistry of Oils and Fats." Thirty weeks on Wednesdays at 6.30 to 9.30 p.m., commencing October 1, 1958.

"The Recent Chemistry and Physics of Waxes." Thirty weeks on Thursdays 5 to 9 p.m., commencing October 2, 1958.

"Some Aspects of Microbiology." Thirty weeks on Tuesdays 6.30 to 9.30 p.m., commencing September 23, 1958.

"Chromatography." Short full-time courses in (a) "Paper Chromatography" and (b) "Paper Chromatography in Clinical Biochemistry" are held at intervals in the Department. Dates will be given on application.

Full particulars from the Principal, Brunel College of Technology, Woodlands Avenue, Acton, W.3 (Telephone Acorn 6661).

OFFICIAL APPOINTMENTS

MANCHESTER COLLEGE OF SCIENCE AND TECHNOLOGY

(Faculty of Technology in the University of Manchester)

LECTURER IN INDUSTRIAL ADMINISTRATION

The Governing Body invites applications for a Lectureship in Industrial Administration in the College of Science and Technology, with the title and status of Lecturer in the University of Manchester. The Department covers a very wide range of aspects of Industrial Administration and all members of staff are expected to undertake, assist in, or supervise research. Executive experience in industry and qualifications in the field of general, social, and industrial psychology are regarded as essential for this post. Salary: According to qualifications, on scale £900 by £50 to £1,350 by £75 to £1,650. Superannuation under the F.S.S.U. Family allowances.

Conditions of appointment and form of application may be obtained from the Registrar, the Manchester College of Science and Technology, Manchester, 1. The last day for the receipt of applications is August 16, 1958.

EXPERIMENTAL OFFICER REQUIRED BY the Atomic Weapons Research Establishment, Aldermaston, Berks. Preferably a graduate Physical Metallurgist or Physicist with an interest in metals, to work on problems associated with fabrication methods and testing of materials. The minimum qualification is G.C.E. in five subjects with English language at "O" level and two mathematical or scientific subjects at "A" level or equivalent qualification. Candidates must be at least 26 years of age. Salary, £990 to £1,215 per annum. Contributory superannuation scheme. A house, or assistance towards legal expenses on house purchase, will be available for married officers living beyond daily travelling distance.—Postcards for application forms to the Senior Recruitment Officer at above address. Please quote ref. 1950/34.

PHYSICIST (SENIOR SCIENTIFIC OFFICER) required by London County Council in the Scientific Branch at County Hall for research work on properties of materials and in the field of health physics. Good honours degree in physics and general physical experience required, with knowledge of radio-chemical equipment. Salary within scale £1,037 10s. to £1,305 according to qualifications and experience. Permanent and pensionable. Good promotion prospects.—Apply to Medical Officer of Health (PH/D.1/A), County Hall, London, S.E.1, by September 1. (1432)

D.S.I.R. ROAD RESEARCH LABORATORY, Harmondsworth, Middlesex, urgently requires Physicists to conduct research on: (1) rheology of solid-liquid systems and viscous and visco-elastic fluids to provide basic information for design of bituminous road mixtures; (2) physical properties of concrete including various aspects of its rheology and effect of changes on construction procedures. Work, varied and interesting, carried out in laboratory and field, and will provide satisfying sense of achievement in solving problems involved. Also provides contacts with other research scientists at home and abroad. Posts are in Scientific and Senior Scientific Officer grades, and require first- or second-class honours degree in physics or equivalent. For Senior Scientific Officer posts some research experience required. Salary within range £635 to £1,410 (men). Prospects of promotion to Principal Scientific Officer in mid-thirties (range up to £2,050 with possibilities of progress). Opportunities for early establishment. Five-day week.—Forms from Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.261/8A.

THE MILK MARKETING BOARD WILL shortly appoint an Experimental Officer to be responsible for the handling and freezing of bull semen at the Board's Deep Freeze Unit at Northampton. Applicants must have a good knowledge of general laboratory technique and experience in the research field is also desirable. The commencing salary will depend on age, qualifications and experience.—Applications, giving full personal details, should be sent to Personnel Officer, Milk Marketing Board, Thames Ditton, Surrey.

AUSTRALIAN NATIONAL UNIVERSITY

CANBERRA

RESEARCH SCHOOL OF PHYSICAL SCIENCES

Applications are invited for the post of Reader, Senior Fellow or Fellow in the Department of Astronomy (Mount Stromlo Observatory). The status of the appointment will depend upon the qualifications of the successful applicant. Preference will be given to an applicant with an interest in the borderline areas of observational and theoretical astrophysics, who can serve as a liaison with the Departments of Nuclear Physics, Particle Physics and Theoretical Physics. Second preference will be given to a candidate distinguished for research in observational and theoretical studies of the Universe of Galaxies. The commencing salary of a Reader is determined within the range £A.2,763 to £A.3,213, and he is appointed to the permanent staff. The salary and range of a Senior Fellow or Fellow are determined within the limits £A.2,553 to £A.3,063 or £A.1,793 to £A.2,563, respectively, and the appointment is made for an initial period of five years; thereafter it may be made permanent. The person appointed will be entitled to one year's study leave on full pay, plus a contribution towards travel and other expenses in every six years (if a Reader or Senior Fellow) or every seven years (if a Fellow). Superannuation on the F.S.S.U. pattern will be provided and reasonable removal expenses will be paid.

Further details are available from the Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1. Applications close, in Australia and London, on September 15, 1958.

GLOUCESTER TECHNICAL COLLEGE

DEPARTMENT OF SCIENCE

A Lecturer in Physics, able to teach up to B.Sc. General and Grad.Inst.P. standard, is required from September 1, 1958, or as soon as possible thereafter. The person appointed will be responsible, under the direction of the Head of Department, for the work in Physics. The salary will be in accordance with the Burnham Scale for Lecturers, viz., £1,200 by £30 to £1,350.

Application forms and further particulars may be obtained from the Principal, Technical College, Brunswick Road, Gloucester, to whom completed forms should be returned as soon as possible.

UNIVERSITY COLLEGE

IBADAN, NIGERIA

Applications are invited for Lectureship (Grade I or II) in Plant Pathology in Department of Agriculture. Initial appointment three years, commencing October, 1958, if possible. Salary scales: Grade I, £1,400 by £50 to £1,650 per annum; Grade II, £1,000 by £50 to £1,300 per annum. Passages paid for appointee, wife and three children under 11 years on appointment, annual overseas leave and termination. Children's, car, and outfit allowances. F.S.S.U. Part-furnished accommodation.

Detailed applications (six copies), naming three referees, by August 25, 1958, to Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1, from whom further particulars may be obtained.

ROYAL NAVAL SCIENTIFIC SERVICE REquires Senior Scientific Officers and Scientific Officers for Establishments in London area, Baldock, Portsmouth, Portland, Poole, Greenock and Rosyth. Main requirements are about 25 vacancies for Physicists, Electronic Engineers and Mathematicians in areas specified. The following particular vacancies also exist: Mechanical Engineer for work on gas turbine problems in the London area. Mechanical Engineers for work on design and development of U/W devices in Portland area. Metallurgists for Rosyth and Poole. Chemists (Physical and Inorganic) for Poole area, Baldock and London. Candidates must normal be natural born British subjects of natural bo British parents, with at least first- or second-cla honours degrees or equivalent high professio attainments. Senior Scientific Officers must had at least three years' postgraduate experi and be not less than 26 years of age. Sal (men): Senior Scientific Officer, £1,190 to £1 Scientific Officer, £635 to £1,110 (London)—s what lower in provinces. Appointments unes lished (with F.S.S.U. benefits), but opportunit may occur for those between the ages of 21 and 32 to compete for established posts.—Forms from Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A98/8A.

TWO NEW JOHN WILEY BOOKS

CONFERENCE ON EXTREMELY HIGH TEMPERATURES

Papers edited by

Heinz Fischer and L. C. Mansur

Size : 11¼ in. by 8⅝ in. 269 *pages* *Illustrated* 78*s. net*

Based on the Conference on Extremely High Temperatures held in Boston in March, 1958, this book is a summary of the underlying basis for commercial or usable thermonuclear reactions. The emphasis is on high temperatures as they relate to the propulsion fields, with rather less emphasis on the physics of the topics covered.

PRINCIPLES OF NOISE

by

J. J. Freeman

(Lecturer in Electrical Engineering, University of Maryland)

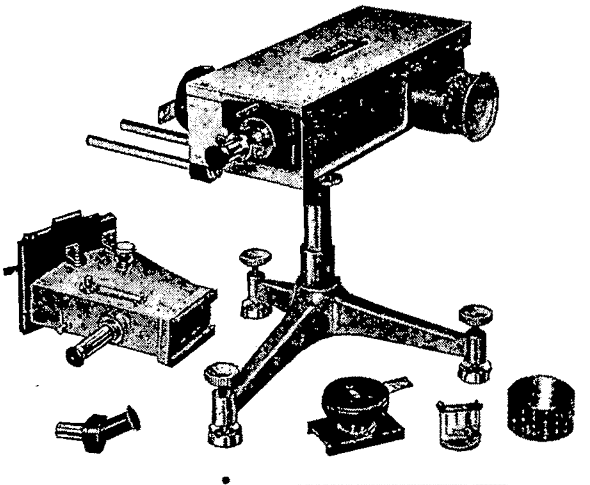
Size : 9¼ in. by 6 in. 309 *pages* *Illustrated* 74*s. net*

This work provides the reader with enough of the principles, facts, and techniques used in noise analysis to take him to the level where he can put the more advanced literature to professional use.

37 ESSEX STREET, LONDON, W.C.2

PRECISION BS INSTRUMENTS

Direct Reading Wavelength Spectrometer



for use in the visible spectrum and also, when required, in the ultra violet and infra red. Reading in wavelengths directly.

A camera attachment can be supplied giving the following length of spectrograms :

With quartz prism, wavelength 10,000 A. to 2,200 A., 70 mm.

With glass prism, wavelength 10,000 A. to 3,600 A., 125 mm.

A large range of accessories can be supplied with this spectrometer, making it a really universal instrument, and our staff will at all times be pleased to recommend the equipment most likely to meet special requirements.

NUCLEAR ENERGY DEVELOPMENT AS A PROBLEM OF MAN-POWER

THE White Paper on "Capital Investment in the Coal, Gas and Electricity Industries"* which was presented to Parliament in April gave the latest information about investment in 1957 together with the approved expenditure for 1958–59. It thus provides something of the background against which to consider the changes in the nuclear power position in Britain since announced, and to which the development of Euratom and particularly the provision of help from the United States have given added interest. Of the approved capital expenditure of £440 million in 1957 compared with an actual £390 million in 1956, £233 million and £206 million, respectively, were on account of the Central Electricity Authority, with a further £20 million and £17 million for the South of Scotland Electricity Board and £21 million and £20 million for the North of Scotland Hydro-Electricity Board. For 1958, out of £436 million approved, the corresponding figures are £239 million, £26·5 million and £17 million, respectively. Of this latter expenditure, no more than some £45·5 million is accounted for by nuclear power stations (including £8·5 million at Hunterston), although in England and Wales estimated expenditure on nuclear stations in 1957–58 was £21 million compared with £37 million approved for 1958–59 and represented continuing work at Bradwell and Berkeley and the commencement of work at Hinkley Point.

As already announced, the White Paper points out that work on new power stations is to be spread over the next 26 instead of 24 months, and the completion of the nuclear power programme is to be postponed for a year, while a higher proportion of the total new generating capacity will be in the form of coal-fired stations at lower capital cost. The decision of the Ministry of Defence that some of the nuclear power stations should be modified to produce plutonium of weapons grade represents, however, a much more considerable modification of the programme. The Paymaster-General, Mr. R. Maudling, explained in the House of Commons on June 24 that the modifications proposed at Hinkley Point and the next two stations in the programme of the Central Electricity Generating Board would not impair the efficiency of the stations and that the initial capital cost and any additional operating costs that may be incurred would be borne by the Government. On June 30 Sir Ian Horobin said in Parliament that the capital cost of the modifications was unlikely to exceed 1 per cent of the cost of the stations concerned and that building progress would not be affected.

While, therefore, the price of electricity may not be affected and the country may in fact be provided at comparatively small cost with a valuable insurance against possible future defence needs, this statement scarcely represents the full implications of this change in design. To obtain plutonium suitable for military purposes, the fuel rods must be renewed at intervals of months rather than of years, and the gross costs will undoubtedly be altered for the worse if fuel costing £10 million or more may all be removed by the end of the year instead of remaining in the reactor for five years. Apart from this, there will be the loss of experience in the probable life of fuel elements; and the processing plants of the Atomic Energy Authority, particularly the diffusion plant at Capenhurst and the chemical treatment plant at Windscale, are likely to be so overloaded that further capital investment by the Authority seems inevitable.

The cost of installing discharging mechanisms and cooling ponds of greater capacity is unlikely to be high, but diffusion plant and chemical treatment plant may be another matter. Serious interference with the nuclear power programme will arise because the plutonium is diverted to military purposes instead of being used to convert infertile material into nuclear fuels. To that extent more uranium will have to be mined and processed, and purchased; and some of the capital on which later reductions in the cost of electricity might be based will in effect be used for that purpose. Moreover, apart from the loss of experience already noted, it is possible that in the immediate future a shortage of plutonium for experimental purposes could retard technical innovations.

Nor is this the whole price to be paid. The rigorous distinction which Britain has hitherto made between its nuclear power programme now disappears, and the dual character of nuclear power stations is, on the contrary, emphasized. This has diplomatic as well as economic drawbacks, and no convincing reasons have yet been given to show that, on balance, the necessary supplies of plutonium would not have been obtained more advantageously by building a new reactor, or by more urgent efforts to utilize the over-abundant stocks built up in the United States—an attempt that the agreement on the exchange of nuclear weapon information signed in Washington on July 3 should facilitate, for it provides specifically for the supply of enriched uranium to the Atomic Energy Authority in Britain.

The change in policy will do nothing to remove the difficulties which it is believed in some quarters that the nuclear power industry is facing. Mr. A. L. G. Lindley, managing director of the General Electric Co., Ltd., expressed the view earlier in the year that no more than six additional orders for nuclear power stations would be placed by the Central Electricity Generating Board in the three years from 1959 compared with the dozen or more additional stations mentioned last year; nor did he expect much profit would accrue to British firms from the export of nuclear power stations, even though many nuclear power stations might be built to British design abroad. On the technical side, too, there is some evidence that builders of nuclear power stations have entered a period of diminishing returns from expenditure on research and development. Sir Christopher Hinton has confirmed this in warning the industry to avoid the difficulties of structure which beset the aircraft industry. From the end of this year, he said, the Board would be placing orders for two main conventional power stations and two nuclear power stations compared with the ten or more power stations ordered every year since the War, the reason being the high capacity of plant which would now be built in a single unit. He thought, too, that within his life-time the future of nuclear power in Britain would be based on developments of the Calder Hall reactor, and he did not expect fusion power of the kind which ZETA may tap to become important industrially for thirty-five or forty years.

---

* Capital Investment in the Coal, Gas and Electricity Industries. Pp. 8. (Cmnd. 415.) (London: H.M. Stationery Office, 1958.) 6*d*. net.

The overdue agreement on the exchange of nuclear information between Great Britain and the United States may prove the latter forecast too pessimistic, for the freer the interchange of information in projects of this type the less likely is progress to be retarded by lack of contact or faulty judgment. Frank and free and informal discussion with other scientists and technologists is the best stimulant of the critical judgment and creative thinking which lie at the root of technological and scientific advance. It should be noted that in replying on an adjournment debate in the House of Commons on March 20, the Parliamentary Secretary to the Ministry of Power, Sir Ian Horobin, was confident that restrictions had not stunted our scientific effort in this field and that we had found happy and practical relations between the Atomic Energy Authority and industry. Whether or not Sir John Cockcroft is right in believing that there is no military use for thermonuclear fusion, scientists should make sure that the utmost use is made of the agreement resulting from the doctrine of interdependence which the Prime Minister and President Eisenhower proclaimed jointly last autumn.

The change in policy may bear equally on Britain's relations with Euratom. Even before the announcement on June 28 that Euratom was to receive massive financial and technical help from the United States, the Government had been for some time closely questioned in Parliament regarding British relations with Euratom. Like other member countries of the Organization for European Economic Co-operation, Great Britain is a member of the European Nuclear Energy Agency, the statute for which was published in a White Paper last February; this provides for close collaboration with Euratom, the members of which are also members of the Agency. On May 22 Mr. R. A. Butler told the House of Commons that the Prime Minister had suggested to the President of the Euratom Commission that, until Euratom had selected its permanent headquarters, the head of the United Kingdom delegation to the High Authority of the Coal and Steel Community should also be accredited to the Euratom Commission. He had also proposed that we should negotiate an agreement for technical collaboration, providing the framework for co-operation between the British Government and Euratom, to facilitate co-operation both between individuals and between individual industrial concerns, and complementary to the general co-operation on nuclear affairs in Western Europe as a whole through the European Nuclear Energy Agency.

Mr. Butler said that these proposals had been welcomed by Euratom, but on June 17 the Prime Minister could only add that preliminary discussion on this technical collaboration agreement were starting that week. On July 1 the Prime Minister said in Parliament that nuclear power plants were unlikely to be bought by the European Atomic Energy Community itself, but rather by individual undertakings in member countries. A number of such inquiries had been received by United Kingdom manufacturers and a letter of intent had been signed between an Italian undertaking and a United Kingdom group. The Government hoped to conclude agreements with the Community and, as appropriate, with member Governments, to provide the framework within which such exports could take place, and such an agreement was already in force with the Italian Government.
